TABLE OF CONTENTS

LIST OF ACRONYMS	vii
SECTION 1.0 – BACKGROUND & APPLICABILITY	1
1.1 – TITLE 200 WORKPLAN APPROVAL & COSTS.....	1
SECTION 2.0 – OVERVIEW OF DEQ’S RBCA PROCESS	3
2.1 – INTRODUCTION.....	3
2.2 – GENERAL RBCA PROCESS.....	3
2.3 – THE INVESTIGATION PROCESS.....	4
2.4 – CHARACTERISTICS OF TIERED PROCESS.....	5
SECTION 3.0 – PRE-INVESTIGATION ASSESSMENT	7
3.1 – SITE ACTIVATION.....	7
3.2 – PRE-INVESTIGATION ASSESSMENT AND SITE VISIT.....	7
3.2.1 – Purpose of Pre-Investigation Assessment & Site Visit.....	7
3.2.2 – Location of Release Source Areas.....	8
SECTION 4.0 – GENERAL RBCA SITE INVESTIGATION REQUIREMENTS	13
4.1 – INTRODUCTION.....	13
4.2 – NATURE OF THE RELEASE.....	13
4.2.1 – Product Released and Chemicals of Concern (COCs).....	13
4.2.2 – Fuel/Waste Oil COCs and Alternative Use of TEH Analysis.....	13
4.3 – SITE INFORMATION.....	15
4.3.1 – Maps.....	15
4.3.1.2 Area Map.....	15
4.3.1.3 Site Map.....	15
4.3.1.4 Free Product Map.....	15
4.3.1.5 Contaminant Plume Maps.....	16
4.3.2 – On-site Ground Water Use.....	16
4.3.3 – Regional Hydrogeology & Aquifer Characteristics.....	16
4.3.4 – GPS Location.....	17
4.4 – ADJACENT LAND USE & RECEPTOR INFORMATION.....	17
4.4.1 – Current Land Use.....	18
4.4.2 – Future Land Use.....	18
4.4.3 – Water Well Survey.....	18
4.4.4 – Subsurface Structures.....	18
4.4.5 – Ecological Exposures Survey.....	19
4.5 – INSTALLATION, DEVELOPMENT, & ABANDONMENT OF MONITORING WELLS.....	19
4.5.1 – Monitoring Well Installation.....	19
4.5.1.1 General Installation Requirements.....	19
4.5.1.2 Auger Drilling.....	19
4.5.1.3 Direct Push.....	19
4.5.1.4 Other Methods.....	20
4.5.2 – Monitoring Well Development.....	20
4.5.3 – Purging of Monitoring Wells.....	20
4.5.3.1 Monitoring Wells in Sands or Gravels.....	20
4.5.3.2 Monitoring Wells in Fine Grained Materials (clays, silts, or very fine sands).....	20
4.5.4 – Abandonment of Monitoring Wells.....	21
4.5.4.1 Request to Retain Monitoring Wells for Subsequent Use.....	21

4.6 – FREE PRODUCT ON GROUND WATER.....	21
4.6.1 – <i>Discovery of Free Product</i>	21
4.6.2 – <i>Minimum Free Product Assessment Data Requirements</i>	22
4.7 – GENERAL SAMPLING REQUIREMENTS	23
4.7.1 – <i>General Subsurface Advancement Methods</i>	23
4.7.2 – <i>Soil Sample Collection Methods</i>	23
4.7.2.1 <i>Sampling of Surface Soils</i>	23
4.7.2.2 <i>Continuous Sampling</i>	23
4.7.2.3 <i>Field Screening</i>	24
4.7.2.4 <i>Soil Sample Collection and Transport for Laboratory Analysis</i>	24
4.7.3 – <i>Ground Water Sample Collection Methods</i>	24

SECTION 1.0 – BACKGROUND & APPLICABILITY

The Petroleum Remediation Section (PRS) of the Nebraska Department of Environmental Quality (DEQ or Department) has compiled this document for the purposes of conducting risk-based corrective action (RBCA) Tier 1 and Tier 2 site assessments and evaluations at petroleum release sites. It has been prepared in accordance with criteria contained in Nebraska Title 118 - Ground Water Quality Standards and Use Classification and Nebraska Title 126 -Rules and Regulations Pertaining to the Management of Wastes. Portions of this document are based on recommendations made by the Technical Advisory Committee created by the Nebraska Legislature, and information contained in the American Society for Testing and Materials (ASTM) Standard E-1739 Standard Guide for Risk-Based Corrective Action Applied at Petroleum Release Sites (ASTM E-1739).

This document is intended to apply to all petroleum releases: those potentially eligible for reimbursement under Nebraska Title 200 -Rules and Regulations for Petroleum Release Remedial Action Reimbursement Fund, as well as those that are not (e.g., pipelines, transportation vessels). This guidance is not intended for investigations of petroleum wastes considered a hazardous waste in accordance with Nebraska Title 128 – Nebraska Hazardous Waste Regulations or a CERCLA-listed petroleum derivative identified in 40 CFR Part 302.

1.1 – TITLE 200 WORKPLAN APPROVAL & COSTS

Costs associated with remedial actions taken due to releases from petroleum leaking underground storage tanks (LUSTs) and leaking aboveground storage tanks (LASTs) are eligible for reimbursement consideration under Title 200. To secure reimbursement consideration for those releases where the Department has required remedial actions, the Department must first approve the responsible parties' (RP) workplans and review the associated cost estimates before any work is performed, unless expressly approved in other Department guidance documents. Performing remedial actions without first receiving approval from the Department may jeopardize Title 200 reimbursement eligibility for those actions.

For petroleum releases not eligible for Title 200, workplans may also be required by the Department.

For petroleum releases, this guidance document may be referenced in the workplan to serve as the description of the procedures that will be followed in the investigation. Any changes from the methods presented in this document must be highlighted and completely explained in the workplan, and they must receive the Department's approval before the investigation begins.

In the event that information specified in the workplan, or in any of the Department's guidance documents referenced by the workplan, is not collected during the assessment or included in the report, that report may be considered incomplete and may not be accepted by the Department. Costs incurred to correct an incomplete report may not be eligible for reimbursement.

The Department also has available the Voluntary Remedial Action (VRA) process whereby the RP does not have to wait for approval of a workplan and may be eligible for reimbursement under Title 200 at a later time. The RP can proceed with appropriate remedial actions following the Department's guidance documents and regulations if the Department has not yet required the RP to take remedial actions. Reimbursement will not occur until the Department requires and approves remedial actions at the site. The release, however, must first be reported to the Department in accordance with Title 126 to be considered eligible for Title 200 reimbursement.

For additional information regarding the Petroleum Remediation program, please view the Department's web page at <http://deq.ne.gov> or call 402/471-2186. For information concerning the VRA process only, contact the Department at 402/471-3093. For additional questions regarding the RBCA program, contact 402/471-2668.

NOTE: The Department is not the sole entity regulating the performance of remedial actions. All investigations, sampling, and other actions must be performed in accordance with either the *Geologists Regulation Act* (Nebr. Rev. Stat. § 81-3501 to § 81-3541) or the *Engineers and Architects Regulation Act* (Nebr. Rev. Stat. § 81-3401 to § 81-3455). In addition, a license issued by the Water Well Standards and Contractors' Licensing Program of the Nebraska Department of Health and Human Services is required for personnel installing water wells and pumps, or collecting samples or measurements from monitoring wells. All other Federal, State, and local laws must also be followed during the course of the RBCA process. Failure to do so may result in Title 200 reimbursement reductions. See Table F-1 for a list of State Agencies and other contacts that may have jurisdiction.

SECTION 2.0 – OVERVIEW OF DEQ’S RBCA PROCESS

2.1 – INTRODUCTION

The term Risk-Based Corrective Action (RBCA) refers to a consistent, methodical decision-making process used to assess actual or likely human and/or environmental risk of exposure to a chemical release and determine appropriate remedial actions in response to such releases. Petroleum releases vary considerably in their potential risk based on a number of variables, including, but not limited to, the type of petroleum product, amount of released product, duration of the release, extent of the release, site geology/hydrogeology, number and type of exposure pathways, and location of human receptors relative to the source. Potential remedial actions may run the gamut from long-term active cleanup to no action. In recognition of this fact, the Department has developed a tiered approach to its petroleum release corrective action process to cost effectively manage impacted sites and focus the finite resources on the more critical sites.

2.2 – GENERAL RBCA PROCESS

The Department’s petroleum release RBCA process follows the general procedures outlined in the governing regulation, Title 118, Appendix B, Steps 6 – 12. Immediate threats from a release are to be mitigated before the site enters the RBCA process. The following steps (also depicted in the form of a flow chart in Figure 2-1) are included in the Department’s RBCA process:

1. Pre-Investigation Site Visit *
2. Tier 1 Site Investigation *
3. Tier 1 Evaluation
4. Tier 2 Site Investigation *
5. Tier 2 Evaluation
6. Remedial Action Conceptual Plan
7. Preparation of Remedial Action Plan *
8. Implementation of Remedial Action Plan *
9. Review of Remedial Action Effectiveness
10. Public Notice and 30-day Comment Period for sites with ground water impact
11. Abandonment of Monitoring Wells and Submittal of Abandonment Forms*
12. Site Closure *

Those steps marked with an asterisk (*) require Department review and approval of workplans and cost estimates prior to work being performed for Title 200 eligible releases. Workplans and cost estimates are not required for work performed under the VRA program, but they may be submitted for review as the Department’s resources allow. Workplans without cost estimates may be required by the Department for non-Title 200 eligible releases.

The responses to discovery of free product, vapors in structures, or surface water impacts are not addressed as separate steps in the RBCA process, but are handled on a case-by-case basis. The unexpected discovery of any of these conditions must be reported to the Department as specified in Table 2-1. These reporting guidelines are in addition to the obligations of the responsible party to report releases according to Title 126.

Table 2-1. Notification of Unexpected Site Conditions at Petroleum Release Investigations

Condition	Notification Timeframe	Contact
Vapors in excess of 1% of the Lower Explosive Limit (LEL) in a building, utility conduit, or other structure Sheen on surface water	Immediate	<ul style="list-style-type: none"> · Local fire department. · State Fire Marshal’s Office (see Appendix F). · DEQ. During business hours, contact ANY project manager in the DEQ Petroleum Remediation Section at 402-471-2186. At any other time, contact the Department’s on-call personnel through the Nebraska State Patrol at 402-471-4545.
Vapors below 1% of the LEL in a building, utility conduit, or other structure	Next business day	<ul style="list-style-type: none"> · Contact ANY DEQ Petroleum Remediation Section project manager at 402-471-2186.
Presence of free product	Next business day	<ul style="list-style-type: none"> · DEQ PRS Project Manager or the Petroleum Remediation Section at 402-471-2186.

The presence of free product often modifies the Tier 1 or Tier 2 investigation requirements, as explained in Section 4.6. In such cases, a report incorporating all other Tier 1 or Tier 2 information, including that for the surface soil, soil leaching to ground water, and inhalation of vapors from subsurface soil pathways, is still required. If necessary, a separate compliance date will be established for submittal of the information required for the suspended pathways.

The time required to complete the RBCA process depends on the amount of contamination present and the complexity of the investigation and, if necessary, remedial actions required. An uncomplicated site that requires only a Tier 1 investigation might achieve closure in five to seven months. If a Tier 2 investigation is required but subsequent remedial actions are not necessary, the process might take up to a year. The anticipated completion time for more complicated sites, or those requiring active remediation, is dependent on the specific site conditions and cannot be generally estimated.

2.3 – THE INVESTIGATION PROCESS

During the Tier 1 investigation, sufficient site data is gathered to establish land use (present and future) in the area around the release site; the location of potential points of exposure, human receptors and pathways; chemical of concern (COC) concentration data in soils and ground water; and certain subsurface physical parameters. This information is used to generate a Site Conceptual Exposure Scenario and determine the appropriate risk-based screening levels (RBSLs) with which to compare the documented site COC concentrations. Data are collected to examine the potential risk of exposure to petroleum contaminants from the following exposure pathways:

- Dermal contact with, ingestion of, and outdoor inhalation through air of COCs from contaminated surface soils;
- Enclosed space inhalation of COCs from contaminated subsurface soils;
- Leaching of COCs from contaminated surface and subsurface soils to ground water;
- Enclosed space inhalation of COCs from contaminated, shallow ground water; and,
- Ingestion of COCs from contaminated ground water.

The purpose of the Tier 2 investigation is to gather additional site COC concentration data and subsurface physical parameter information that is more detailed than that gathered during the Tier 1 investigation. This information is used to generate site-specific target levels (SSTLs) that are compared to representative site COC concentrations for the completed exposure pathways from Tier 1. All COCs and all complete routes of exposure will be evaluated during the Tier 2 phase.

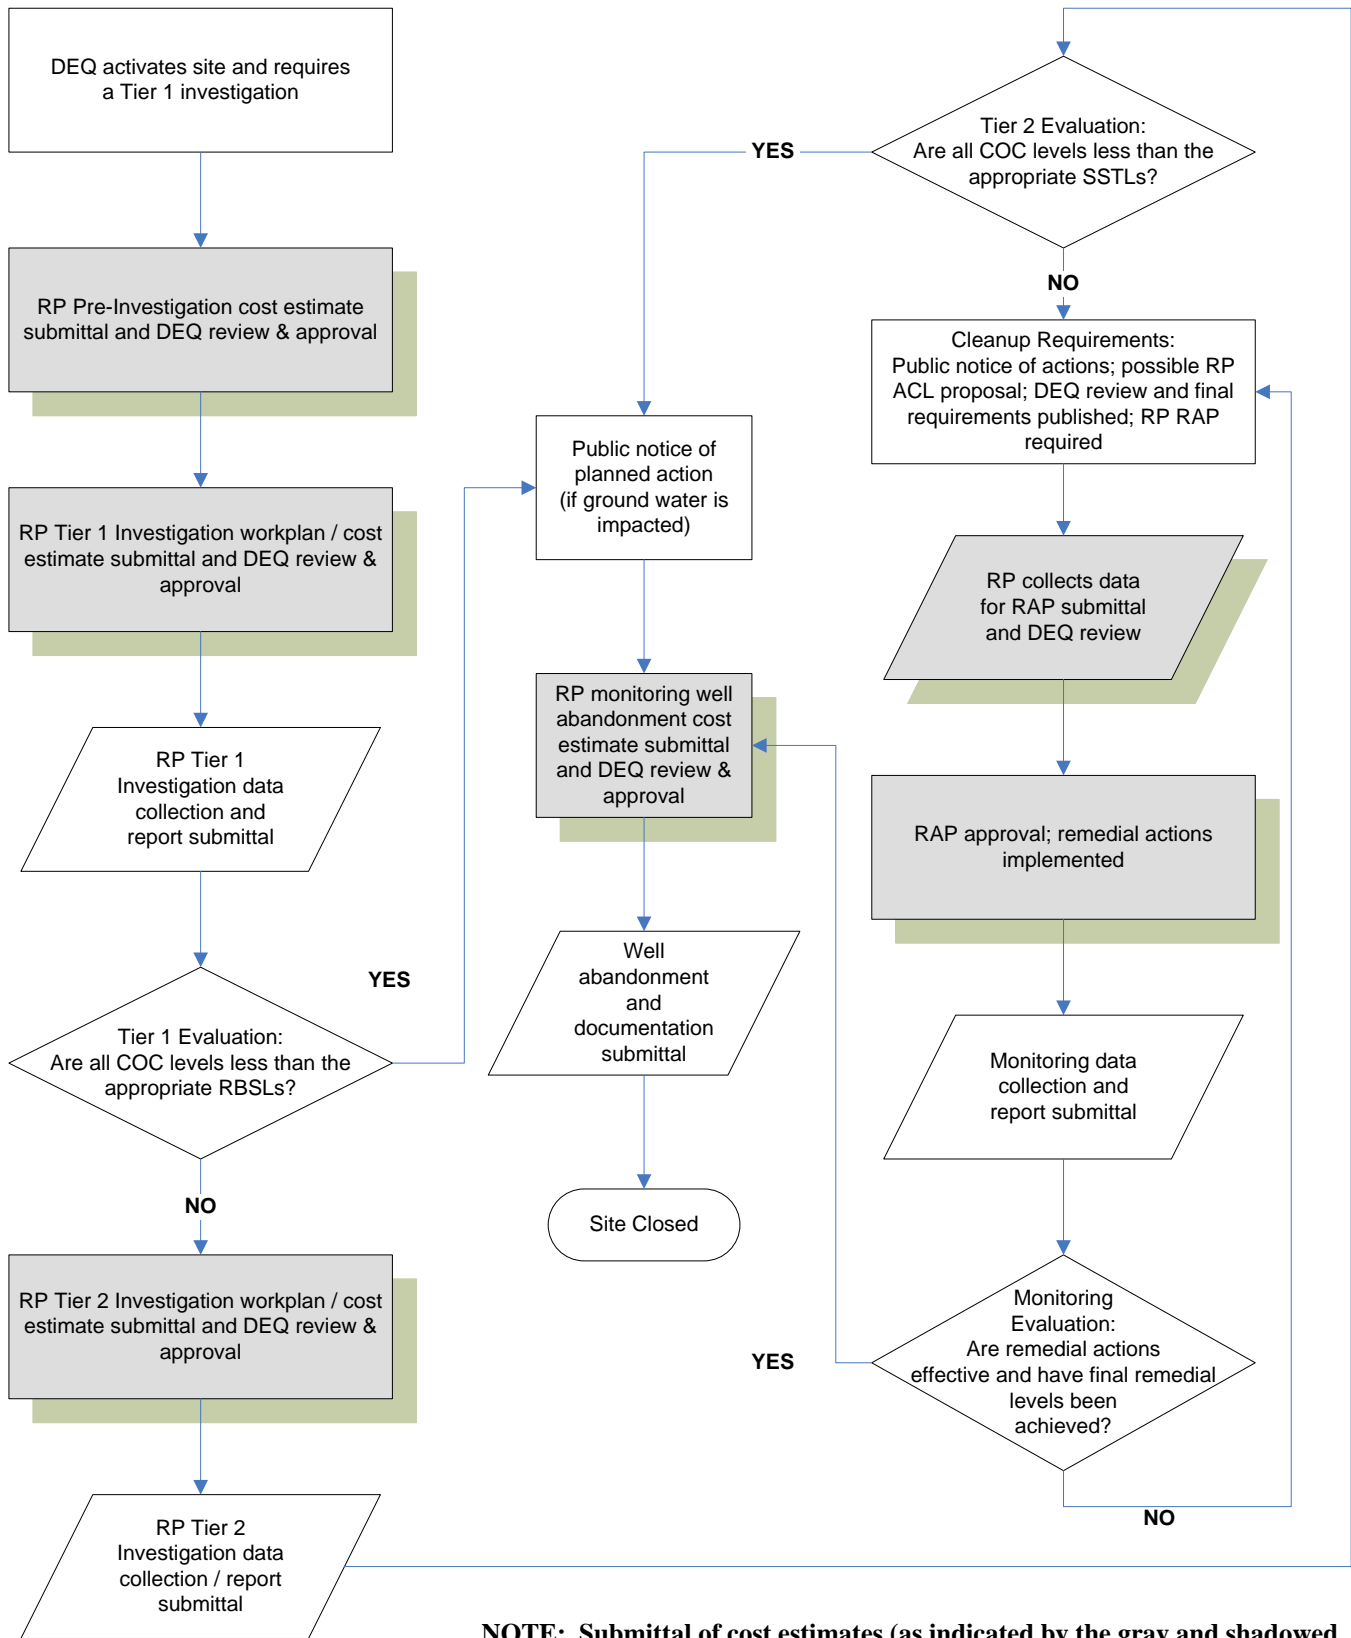

2.4 – CHARACTERISTICS OF TIERED PROCESS

As defined in ASTM E-1739, a Tier 1 evaluation is “a risk-based analysis to develop non-site-specific values for direct and indirect exposure pathways utilizing conservative exposure factors and fate and transport [models] for potential pathways and various property use categories ... Values established under Tier 1 will apply to all sites that fall into a particular category.” (“Direct exposure” indicates that the point of exposure is at the source of the release; “indirect exposure” indicates the existence of an intervening medium of transport between the source and a point of exposure.)

A Tier 2 evaluation is a risk-based analysis applying the same exposure factors and models used for the Tier 1 evaluation but incorporating more site-specific data to develop site-specific target levels for all COCs and all complete exposure pathways.

Based on these definitions, certain general statements can be made when comparing the individual tiers. First, when proceeding from Tier 1 to Tier 2, the amount of data collected during the investigation phase increases. Additional work in the Tier 2 phase may include more complete soil sampling, additional ground water sampling and/or subsurface physical/chemical parameter testing. Second, as more data is collected, the level of conservatism used in the evaluation of the data usually decreases. This means that the Tier 2 SSTLs will generally be greater than the Tier 1 RBSLs for the same site. However, the target risk or level of protection remains the same for both tiers.

Figure 2-1. Generalized DEQ RBCA Process Flow Chart

NOTE: Submittal of cost estimates (as indicated by the gray and shadowed boxes) will not be required for sites not eligible for T200 reimbursement.

SECTION 3.0 – PRE-INVESTIGATION ASSESSMENT

3.1 – SITE ACTIVATION

Upon activating a petroleum release site for a RBCA Tier 1 investigation, the Department notifies the responsible party (RP) in writing of its requirements. For sites eligible for Title 200 reimbursement, the first of these requirements is the submittal of the Department's Tier 1 Pre-Investigation Assessment Work Plan Form, including a cost estimate to conduct a pre-investigation assessment as described in Section 3.2.1 below. Depending on the extent of the release, the Department may not require a pre-investigation assessment for non-Title 200 eligible releases. The Pre-Investigation Assessment Work Plan Form is to be submitted within the time schedule set by the Department.

3.2 – PRE-INVESTIGATION ASSESSMENT AND SITE VISIT

An assessment of the current site conditions is necessary for sites entering the RBCA process. Prior to conducting a RBCA Tier 1 site investigation, the Department requires that a pre-investigation assessment, including a site visit, be performed by the consultant. Work on the assessment must not begin until the Department has approved the Pre-Investigation Assessment Work Plan Form.

3.2.1 – Purpose of Pre-Investigation Assessment & Site Visit

The purpose of this assessment and site visit is to:

1. Conduct a file review and an on-site reconnaissance to determine the number and location of potential source areas, and potential complications for sampling the source areas.
2. Locate any water supply wells as described in Section 4.4.3.
3. Locate any surface water bodies within 1000 feet of the site.
4. Contact One-Call and conduct an on-site utilities survey (including UST leak detection and leak prevention equipment) as an aid in determining potential site complications.
5. Determine the appropriate sampling and/or drilling locations to obtain the required COC concentrations. Consultants must ensure that such potential monitoring well locations are accessible (landowner's permission as well as equipment access).
6. Prepare a site map (to scale) showing the following features. If any are not present, explain in the narrative.
 - potential source areas
 - selected sampling and/or drilling locations
 - water supply wells within 200 feet of the site
 - buildings within 200 feet of the site
 - basements within 200 feet of the site
 - utilities within 200 feet of the site
 - surface water bodies within 200 feet of the site
 - tank system (current and former) locations, including tanks, piping, dispensers, and leak detection and prevention equipment
 - area(s) of any surface staining
 - anticipated ground water flow direction

NOTE: Selection of boring locations at facilities with any storage tanks (underground or aboveground) should be made with caution. Underground piping is typically non-metallic and may not be locatable. Steel tanks and piping may also be equipped with cathodic protection (CP). These CP systems may have wiring from the building to an anode bed surrounding the tanks and piping. “As-built” drawings are required to be kept at the tank location for location purposes prior to beginning any work. If you have any questions regarding these issues, please contact the State Fire Marshal’s Fuel Safety Division at 402/471-9465. Also, please keep in mind that for any subsurface investigation, “One Call” procedures need to be followed for locating utility services.

Acquiring access to prospective drilling locations is a key purpose of the pre-investigation assessment and site visit. Obtaining permission from property owners in advance helps ensure that field work can be completed quickly and efficiently, and every effort must be made to secure the necessary agreements before proceeding. If a property owner refuses to grant permission for access and no suitable alternative location is available, the PRS Project Manager should be contacted as soon as possible for assistance. The property owner’s name, phone number, and the location of the property in question should be provided.

Payments to neighboring property owners for site access are generally not eligible for T200 reimbursement. When access is needed to railroad property, the railroad should be informed that the Department is requiring the remedial action because there are agreements in place to waive some of the fees. The PRS Project Manager should be contacted to discuss the specific situation.

Upon completion of the pre-investigation assessment, a Tier 1 Investigation Work Plan Form, the above referenced site diagram, and a proposed cost estimate for a complete Tier 1 site investigation are to be submitted to the PRS Project Manager for review.

3.2.2 – Location of Release Source Areas

Maximum COC concentrations are assumed to occur at the source areas. Therefore, the identification of source areas is of primary importance to the investigation. For the purposes of this document, source areas are determined as:

1. Areas surrounding documented points of leakage, such as holes in a tank or piping, leaking pipe joints as documented in a LUST/LAST removal/upgrade report, or overfills at other specific points such as dispensers or load out racks;
2. Visually discolored or stained surface and subsurface soils;
3. Elevated field screening levels and/or analytical sampling results compared to other areas documented during the tank removal/upgrade or subsequent to any other release event; and/or,
4. Any other known locations of a spill.

For service station sites where multiple holes are documented in one tank or in adjacent tanks, the tank area may be considered as one source area. In cases where an RP or their consultant believes the source area(s), as defined above, cannot be reasonably determined or believes the proximity of potential source areas may otherwise dictate a lesser number of sampling locations, the RP or their consultant should consult with the Department to select the appropriate number and location of sampling areas.

In cases where site conditions preclude investigation directly through a source area (e.g., a new building or building addition sitting over the former tank excavation location, concrete debris from tank removal disposed in former tank excavation, presence of utilities, lined secondary containment areas), the Department must be consulted in order to determine the appropriate number and location of sampling areas. Variables used in this discussion may include, but are not limited to, the degree of obstruction, expected ground water flow direction and depth to ground water. In extreme cases, the Department may consider alternatives to this document, such as sampling and monitoring of soil vapor and/or indoor air.

See Figure 3-1 for examples of source area(s) selection for various petroleum release scenarios.

Figure 3-1. Example Selection of Source Areas for Various Petroleum Releases

Figure 3-1a. This generalized LUST site layout (not to scale), based on a hypothetical Closure Assessment Report, provides an idealized example of determining potential source areas for monitoring well installation when conducting a RBCA Tier 1 investigation. The numbers along the product lines represent field screening measurements. The source areas are based on:

- 1) a documented point of leakage (corrosion holes) in one of the USTs, and
- 2) elevated field screening levels/laboratory analyses associated with a joint in the product piping.

Note the placement of an upgradient and downgradient monitoring well. The downgradient well should be downgradient from the point of highest source area contamination. The upgradient well should be located to best allow the ground water flow direction to be determined.

Figure 3-1b. Generalized AST release with no secondary containment around the ASTs. The actual number of source area borings (denoted by the stars within the spill area) will vary based on the size of the spill area and consultation with the Department. For such a surface release, low-lying areas where product may pool are likely candidates for boring placement. Also, this site contains a bulk load-out rack area where an unknown number of petroleum overfills have occurred and would need to be assessed during a Tier 1 investigation. Note the placement of an upgradient and down gradient monitoring well.

Figure 3-1c. Generalized AST bulk facility with lined secondary containment. To maintain the integrity of the liner, borings are generally not required within the secondary containment area. The actual number of source area borings/monitoring wells (denoted by the stars within the spill area) will vary based on the size of the spill area and consultation with the Department. For such a surface release, low-lying areas where product may pool are likely candidates for boring placement. Note the placement of an upgradient and down gradient monitoring well.

Figure Key

- AST (no sign of leakage)
- Leaking AST
- Rainwater gate
- Spill area / surface contamination
- Boring / monitoring well location

Figure Not To Scale

Figure 3-1d. Generalized transportation incident resulting in large volume petroleum release. This release would be ineligible for Title 200 reimbursement. The actual number of source area borings/monitoring wells (denoted by the stars within the spill area) will vary based on the size of the spill area, the surface sample analytical results, and consultation with the Department. For such a surface release, low-lying areas where product may pool are likely candidates for boring placement. An upgradient monitoring well is not needed unless there is reason to suspect that previous contamination may be present.

Figure Not To Scale

Figure Key

Figure Key

-  Point of pipeline "blowout"
-  Spill area / surface contamination
-  Boring / monitoring well location

Figure Not To Scale

Figure 3-1e. Generalized high-volume pipeline "blowout" resulting in large volume petroleum release with an area of contaminated surface soils. This release would be ineligible for Title 200 reimbursement. The actual number of source area borings/monitoring wells (denoted by the stars within the spill area) will vary based on the size of the spill area and consultation with the Department. For such a surface release, low-lying areas where product may pool are likely candidates for boring placement. Upgradient and downgradient monitoring wells should be included.

Figure Not To Scale

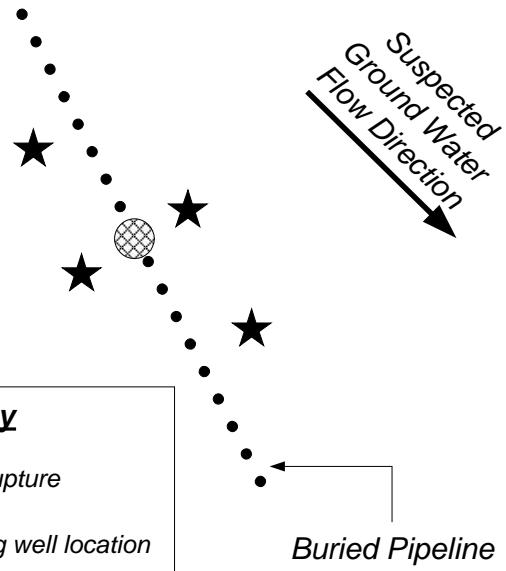

Figure Key

-  Point of pipeline rupture
-  Boring / monitoring well location

Figure 3-1f. Generalized high-volume pipeline release with limited or no contaminated surface soils. The immediate vicinity of the point of pipeline rupture would be considered the source area. A minimum of four borings/monitoring wells would be placed around the point of release, including upgradient, downgradient, and both cross-gradient locations. This release would be ineligible for Title 200 reimbursement.

SECTION 4.0 – GENERAL RBCA SITE INVESTIGATION REQUIREMENTS

4.1 – INTRODUCTION

Section 4.0 provides guidance regarding information required for both Tier 1 and Tier 2 investigations. Such information includes selection of COCs, general site and area information, evaluation of ground water and land use, water supply well information, free product requirements, general sampling requirements, and saturated zone characteristics.

If free product, a sheen on surface water, or petroleum vapor accumulations in structures or utility conduits are encountered at any time during the investigation, the Department must be contacted as specified in Table 2-1.

4.2 – NATURE OF THE RELEASE

4.2.1 – Product Released and Chemicals of Concern (COCs)

The petroleum products released to the environment are to be identified based on the spilled material reported to the Department, the documented presence of chemical components found in various petroleum products, and/or the available product storage history and points of leakage information documented in the Department's petroleum release file. This information is used to determine the appropriate COCs for which sampling must be performed during the site investigation.

This guidance is written to address releases of petroleum, petroleum distillates, petroleum additives, and waste oil. The COCs typically sampled for most petroleum releases are provided below in Table 4-1. To assess the overall degree of petroleum contamination at the site, a total gross hydrocarbons analysis will also be required for middle and heavy distillates.

Allowable laboratory analysis methods for these COCs are also provided in Table 4-1. The contracted laboratory must be able to achieve the minimum quantification levels that are found in Table 4-1. The Department has no lab certification program, but laboratory analysis of soil, ground water and/or vapor samples by laboratories certified by the National Environmental Laboratory Accreditation Conference (NELAC) is recommended.

4.2.2 – Fuel/Waste Oil COCs and Alternative Use of TEH Analysis

RBCA requires that laboratory detection levels for COCs be below the potential target levels (i.e., the RBSLs and SSTLs). This is problematic for some of the polynuclear aromatic hydrocarbon (PAH) COCs, particularly benzo(a)pyrene which has a Maximum Contaminant Level (MCL) (and corresponding RBSL for the ground water ingestion pathway) of 0.0002 mg/L.

In recognition of this potential dilemma, the Department has developed an alternative to a chemical-specific detection method for the specified PAHs. The alternate methodology takes a surrogate approach where TEH levels are used to estimate the on-site concentrations of the PAH COCs, based on a percentage of the particular COC in the original product. A more detailed discussion of this surrogate method can be found in Appendix A.

At the Tier 1 level, all PAHs are evaluated based on the TEH surrogate method. Therefore, the Department will not require chemical-specific analysis for the PAH COCs.

For the Tier 2 process, where SSTLs are developed, a somewhat different approach is taken. Based on the information provided in Appendix A, the PAH COC driving the evaluation of diesel fuel is naphthalene. For waste oil, it is benzo(a)pyrene (BaP). **For the evaluation of diesel fuel (and other middle distillates) at the Tier 2 level, the Department will require chemical-specific sampling for naphthalene.** This will allow for a more accurate evaluation of naphthalene and a more reasonable determination of appropriate SSTLs. For waste oil releases, the Department will still use the TEH surrogate method to establish SSTLs, and sampling for BaP is not necessary.

Table 4-1. Chemicals of Concern for Different Petroleum Product Releases

Chemical of Concern	Gasoline and JP-4	Diesel, #2 Fuel Oil, Kerosene, Other Jet Fuels	Heavy Distillates	Waste Oil	Acceptable Test Method(s) ^{1,2}	Minimum Quantification Level		
						Water (mg/L)	Soil (mg/kg)	Soil Gas ¹² (mg/m ³)

Total Extractable Hydrocarbons (TEH)		X	X	X	OA-2 ^{4,6,8} , 8015B ^{3,6} (based on product type)	1.000	10.000	700
OTHER POTENTIAL ANALYTES⁵								
Chlorinated Solvents				X				
Ethylene glycol				X				
Metals				X				

ABBREVIATIONS:

X: COC to be analyzed
 MTBE: Methyl Tertiary-Butyl Ether
 N/A: Not Applicable; COC Screening Levels based on TEH Concentration

NOTES:

- ¹ The Department recommends consulting with a NELAC laboratory prior to collecting samples to determine its ability to analyze for the COCs.
- ² Other test methodologies not listed here may be appropriate for a specific COC. If an alternate methodology is desired, a prior written request must be submitted to the Department with appropriate supporting material.
- ³ Methods promulgated by USEPA. Specific information regarding these methods can be found in EPA SW-846 Test Methods for Evaluating Solid Waste.
- ⁴ The Iowa Hygienics Laboratory (IHL) methods OA-1 and OA-2 are not EPA promulgated methods, but the Department has approved them for use. Method OA-1 will analyze specifically for the BTEX compounds; Method OA-2 is to be used with the TEH surrogate method.
- ⁵ The need to sample and analyze for these chemicals will be determined on a case-by-case basis as dictated by the product storage history and approved by the Department.
- ⁶ The most current test method revision should be used for analysis. For method OA-1, your laboratory of preference must strictly adhere to the method as developed and written by the IHL, not a modified version of OA-1 unless approved by the IHL.
- ⁷ Also refer to discussion in Section 4.2.2.
- ⁸ When utilizing Method OA-2, request the laboratory to use the standard for those "heavy" petroleum products that were or may have been released, but not specifically mentioned in Table 4-1, such as naphtha, Stoddard solvent, motors oils, home heating and fuel oils, hydraulic oil, etc. Analysis for TEH(gasoline) is not required.
- ⁹ The Department has approved the use of OA-1 and Method 8260 for volatile analysis. However, if MTBE is present in the sample (identified with the GC), we require that an MS (not an FID or PID) be used to quantify the MTBE. If MTBE is not present, the use of an MS is not necessary to quantify the remaining COC volatiles (benzene, toluene, ethylbenzene, total xylenes, n-hexane, and PAHs) that might be present in the sample.
- ¹¹ Method TO-15 is acceptable only for soil gas samples, not for water or soil.
- ¹² If the Department requires analysis of indoor air samples, the minimum quantification levels will be: n-hexane – 0.200; benzene – 0.0003; toluene – 0.100; ethylbenzene – 0.006; total xylenes – 0.18; MTBE – 0.0045; naphthalene – 0.0007. (all concentrations in mg/m³)

4.3 – SITE INFORMATION

4.3.1 – Maps

A number of maps depicting a variety of relationships between the release and the affected environment and potential receptors must be prepared for the investigation report. **Aerial photographs may be submitted in addition to, but are not to be used as a substitute for, any of the required maps.** General and specific map requirements are provided below.

4.3.1.1 General Map Requirements

Maps may be in 8.5- by 11-inch format or 11- by 17-inch format. All structures and other physical features depicted on the map must be based on current field information gathered during the pre-investigation site visit.

Maps are to be to scale and include:

1. north arrows;
2. the location of the permanent to semi-permanent benchmark used for site measurements and elevations;
3. numeric and bar scales; and,
4. a legend which includes the site name, Department spill file number, map title, map date and explanation of any symbols used.

4.3.1.2 Area Map

The Area Map is to be a general map showing the location of the facility within the bounds of the community or area in which it is found (e.g., from a USGS topographic map). In addition to the general map requirements listed above, this map must show the location of all water supply wells as designated under Section 4.4.3, all surface water bodies within 1000 feet, and all dwellings and sensitive population centers (see also Section 4.4.1) within 500 feet of the site's source area(s).

4.3.1.3 Site Map

The Site Map is to be a larger scale map providing detail of the area within approximately 200 feet of the facility's source area(s). In addition to the general map requirements listed above, this map must provide the location of all subsurface structures and utilities, any water supply wells, any surface water bodies, any dwellings and sensitive population centers, all sampling point locations (including vapor assessment locations) and the ground water flow direction within this area (including ground water elevation contours). The date of the ground water elevation measurements used to determine the flow direction is to be included in the legend. If source area GPS coordinates are collected (see Section 4.3.4) the points at which the readings were taken should be clearly indicated on the site map.

4.3.1.4 Free Product Map

The Free Product Map, drawn to the same scale as the Site Map, is to provide details on the location, orientation, and apparent free product thickness of a free product plume. The Free Product Map is required only in instances where a measurable (≥ 0.01 feet) thickness of free product is present in one or more monitoring wells. In addition to the general map requirements listed above, this map must provide isopleths for plume thickness, the location of all buildings, subsurface structures and utilities, any water supply wells, any surface water bodies, any sensitive population centers, all sampling point locations (including vapor assessment locations), and the area ground water flow direction.

4.3.1.5 Contaminant Plume Maps

Tier 1 investigations: Because sampling locations are limited and the extent of contamination has not been defined, Contaminant Plume Maps are not required for Tier 1 investigations.

Tier 2 investigations: Contaminant Plume Maps are to be provided for each media being investigated (i.e., ground water, subsurface soils, soil vapor) for each individual COC with concentrations exceeding the values presented in Table 4-2. If analytical results indicate that all concentrations of a COC are below the levels specified, no map should be submitted for that COC and media. Maps are to be drawn to the same scale as the Site Map and must provide details about the location, orientation, and quantitative sampling results of the COCs under investigation. Each map must include all analytical sampling results as well as isoconcentration lines for the lateral extent of the specific COC. Use dashed isoconcentration lines wherever data points are lacking and the information is inferred. In addition to the general map requirements listed above, these maps must provide the location of all buildings, subsurface structures and utilities, any water supply wells, any surface water bodies, any sensitive population centers, all sampling point locations (including vapor assessment locations) and the ground water flow direction within this area.

Table 4-2. Minimum Concentrations for Contaminant Plume Maps

Contaminant of Concern	Media Affected	
	Ground Water (mg/L)	Subsurface Soil (mg/kg)
Benzene	0.005	0.014
Toluene	1.0	8.510
Ethylbenzene	0.700	4.370
Xylenes	10.0	147.0
n-Hexane	4.0	N/A ¹
MTBE	0.020	0.022
Naphthalene	0.020	1.0
TEH (as Diesel fuel)	10.0	770.0
TEH (as waste oil)	6.666	152,666.0

NOTES:

¹ Not Applicable; the target level is not exceeded for all possible saturated levels in soil. ||

4.3.2 – On-site Ground Water Use

Information is to be provided regarding ground water use within the property boundaries of the release site. Documentation of this information is to include the number and use of any water supply wells, as well as any information regarding the construction and production capacities of the wells (depth, screened interval, diameter, etc.). If no on-site water supply wells exist, information is to be provided regarding the on-site water supply source.

4.3.3 – Regional Hydrogeology & Aquifer Characteristics

Information is to be provided regarding the regional hydrogeology and nature of the underlying aquifer. This information includes, but is not limited to, depth to ground water, seasonal fluctuations, regional ground water flow direction, controls over ground water flow in the area (e.g., recharge areas, large expanses of paving, open drainage ditches, or nearby gaining or losing streams), subsurface sediment types, and aquifer thickness and aquifer parameters (e.g., hydraulic conductivity, transmissivity, storativity). Potential sources of this information include, but are not limited to the USGS and the University of Nebraska Conservation and Survey Division.

4.3.4 – GPS Location

The Department requests that an accurate location for the site and each source area be determined using a Global Positioning System (GPS) receiver. Locations for individual monitoring wells may also be collected, but are not required. The results are to be included on Tier 1 Report Form 3b or Tier 2 Report Form 1b in decimal degrees of latitude and longitude, reported to at least six decimal places (i.e., 99.123456). Supporting information to be provided on the form includes:

- The manufacturer and model number of the GPS receiver used.
- The datum used by the unit. The Department prefers either WGS84 (the typical manufacturers' default setting) or NAD83.
- The unit's WAAS (Wide Area Augmentation System) status: enabled (preferred), disabled, or N/A.
- The numerical accuracy of the location coordinates, if available. While the use of recreational-quality GPS units is adequate for site and source-area locations, the Department recommends using a unit that provides sub-meter accuracy if individual well locations are collected.
- A description of the point at which the coordinates were collected.

The location(s) where GPS readings were taken should also be included on the site map.

The location chosen for source area coordinates is to be as close as possible to the point of highest reported contamination within each identified source area. The general site location coordinates may be collected at either or both of the following locations:

- The intersection of the facility driveway with the closest public street, road, or highway
- Immediately outside the main office of the facility

When collecting the location coordinates, the Department recommends that the GPS unit be placed on a stationary surface and left in place for several minutes. Close proximity to trees, buildings, vehicles, and other objects should be avoided if possible as they may affect the quality of the received signal.

4.4 – ADJACENT LAND USE & RECEPTOR INFORMATION

The concept of risk-based investigations requires an understanding of the ideas of receptors and points of exposure. For the purposes of this document:

“**Receptor**” refers to any humans potentially exposed acutely (short-term) or chronically (long-term) to any COCs from a petroleum release.

“**Points of Exposure**” (POE) refers to the locations at which the receptor is potentially exposed, such as water wells or basements. POEs may be actual or hypothetical (future-use) locations, depending on ground water use or the location of structures in the area.

“**Ecological Exposure**” refers to locations where the COCs or free product from a petroleum release contact a lake, stream, wetland, or other surface water body with the potential to affect wildlife.

In order for the Department to evaluate the potential impacts to POEs and the consequential risk to humans, information must be collected about a variety of areas as described in the following sections.

4.4.1 – Current Land Use

Information regarding land use in the area around a petroleum release is needed for site evaluation and determination of the appropriate RBSLs and SSTLs. At the RBCA Tier 1 level, the Department classifies each release site as “Residential” or “Commercial” based on land use within a 500-foot radius of the site. “Residential,” for the purposes of this document, refers to the presence of dwellings (e.g., houses, apartments) and/or sensitive population centers (e.g., schools, day care centers, hospitals, nursing homes). Sites that cannot be classified as residential, based on the preceding definition, are characterized as being in a “Commercial” setting.

At the RBCA Tier 2 level, on-site and off-site land use will be determined on a site-specific basis for properties directly or potentially affected by the petroleum release.

4.4.2 – Future Land Use

The potential for future changes in area land use must be considered during the data collection process. The current property owner is to be interviewed regarding planned development or land use changes that would affect the property’s classification as residential or commercial. Any planned or proposed changes must be documented in the report.

4.4.3 – Water Well Survey

Information regarding the location and distance of water supply wells must be gathered. Water supply wells include municipal, domestic, irrigation, industrial, and agricultural water wells. This definition also includes sand points, hand-pumped wells, etc., used in activities such as, but not limited to, lawn irrigation or as a park water supply. The RP/consultant is to collect information on:

- all municipal wells within 2000 feet of the source area(s),
- domestic, irrigation, industrial, and agricultural wells within 1000 feet, and
- sand points and hand-pumped wells within 500 feet.

The information must include the owner of the well and, where available, the depth, screened interval, type and duration of use, and Nebraska Department of Natural Resources Registration number (see Appendix F for contact information).

Unregistered wells may be present. The local Water or Utility Superintendent must be contacted and asked about the presence and locations of unregistered domestic or other wells. The full name of the person contacted and the conversation date must be documented in the report. A visual survey of properties within 200 feet of the source (Tier 1) or within 200 feet of the maximum extent of soil contamination, free product, or dissolved contamination in ground water (Tier 2) must also be conducted to verify the presence or absence of unregistered wells. Contact the property owner(s) if necessary. The unregistered well survey should be made in conjunction with the subsurface structures survey (Section 4.4.4).

At the Tier 1 level, all water supply wells described above are treated as potential points of exposure (POEs). At the Tier 2 level, only those water wells that influence or are threatened by the contaminant plume are considered potential POEs.

4.4.4 – Subsurface Structures

Identify the location and depth of all subsurface structures within 200 feet of the source (Tier 1) or within 200 feet of the maximum extent of soil contamination, free product, or dissolved contamination in ground water (Tier 2). Subsurface structures include buildings with basements or crawl spaces, cellars, storm or sanitary sewer lines, utility conduits, or any other man-made space that might allow the accumulation of vapors from the release. Consult the local utility superintendent and conduct a visual survey of properties to verify the presence or absence of basements or other subgrade structures. Contact the property owner if necessary. The subsurface structures survey should be made in conjunction with the unregistered well survey (Section 4.4.3).

4.4.5 – Ecological Exposures Survey

Permanent surface water bodies within 1000 feet of the source (Tier 1) or within 1000 feet of the maximum extent of soil contamination, free product, or dissolved contamination in ground water (Tier 2) are to be visually inspected for petroleum sheens possibly emanating from the source. Permanent surface water bodies refer to any river, stream, lake, pond, wetland, sand pit, quarry or similar water body which is likely to have water year round or a significant portion of the year. All surface water bodies must be assessed for the presence of free product, petroleum sheen or petroleum contaminated seeps. When any of these situations are encountered on or in surface water, the PRS Project Manager must be contacted by the next business day. The need for additional assessment of these surface water bodies or other potential ecological exposures (e.g., endangered or threatened species considerations) will be determined by the Department.

4.5 – INSTALLATION, DEVELOPMENT, & ABANDONMENT OF MONITORING WELLS

4.5.1 – Monitoring Well Installation

All boring and monitoring well installation methods must adhere to the criteria described below. Monitoring wells are to be constructed as directed under Nebraska Title 178 – Environmental Health (administered by the Nebraska Department of Health and Human Services). Any regulatory variances from Title 178 must be approved by DHHS in advance and documented in the workplan and report.

4.5.1.1 General Installation Requirements

Monitoring wells must be a minimum of 2 inches in diameter. Screen length for all monitoring wells is not to exceed 10 feet without prior approval. Screens are to be commercially-slotted or continually-wrapped schedule 40 PVC. Monitoring wells should be constructed so that the anticipated static ground water level intersects the midpoint of the screened interval. In cases where seasonal or other fluctuations of the ground water table are anticipated, the range of expected fluctuations must be stated in the workplan. In those instances the Department may approve a longer screen length or require the installation of additional monitoring wells to address the anticipated fluctuations.

NOTE: For the annular seal of wells screened at or above the ground water table, the Department recommends the use of bentonite chips or a slurry containing cement. Wells screened below the water table should be sealed using bentonite granules or a cementaceous slurry. The use of a bentonite-only slurry is discouraged because it does not provide as many solids in the annular space. At the time of this writing the use of bentonite chips for the annular seal has not yet been incorporated into Title 178, so a regulatory variance must be obtained in advance from DHHS.

4.5.1.2 Auger Drilling

A hollow stem auger is the preferred drilling method for environmental assessments. Solid stem augers may be used only for those monitor wells installed away from known source areas, when the material being drilled will maintain its integrity throughout the length of the boring without the aid of outside support, and **only** after Department approval. If there is any chance the borehole will distort (i.e., cave, heave, slough, etc.), solid stem augers are not to be used. Samples must be collected ahead of the drill string when either auger drilling method is used (see Section 4.7.2.2).

4.5.1.3 Direct Push

Direct push technologies cannot be used for Tier 1 investigations. They are acceptable for Tier 2 investigations for soil vapor assessment (see Section 4.7.4), provided that analysis of vapors is performed in accordance with Section 6.3.1, or for soil and ground water assessment, provided that they allow for the collection of all data required under this section and do not violate Title 178 requirements. Use of a direct push technology for the installation of permanent ground water monitoring wells is currently not an acceptable method under Title 178.

4.5.1.4 Other Methods

Air rotary, mud rotary and/or cable tool drilling methods may be necessary in certain circumstances (e.g., excessive ground water depth, near surface bedrock). However, such methods generally preclude the collection of soil samples as required by the Department. In such cases, either hollow stem augers will need to be used in conjunction with the alternate drilling method for subsurface soil sampling or the consultant must provide adequate evidence that the required and representative soil samples can be collected using the alternate drilling method. Contact the PRS Project Manager for approval of alternate drilling methods and additional requirements.

4.5.2 – Monitoring Well Development

While there is some debate regarding the effectiveness of well development on monitoring wells that straddle the water table and/or are installed in fine-grained materials, Nebraska Title 178 requires that all cased water wells be developed. Monitoring wells are to be developed using a method that will maintain the integrity of the well materials. Well development is to continue until visibly clear water is discharged from the well or until indicator parameters (i.e., temperature, pH, conductivity) have stabilized. Any drilling method that involves the use of drilling fluids (e.g., mud rotary or head of water on hollow stem augers) must account for the volume of the fluid used when developing the well.

Sufficient time must be allowed following monitoring well installation and/or development in order for ground water in the well to reach equilibrium conditions before ground water samples for analytical analyses are collected. This time will vary based on site-specific conditions and will be at the discretion of the consultant. Well development does not suffice as a purging event.

4.5.3 – Purging of Monitoring Wells

4.5.3.1 Monitoring Wells in Sands or Gravels

Monitoring wells screened entirely or partially in sands or gravels and sampled for dissolved phase contaminants must be purged prior to sample collection, but should never be purged dry. Allowable purging methods are:

- pneumatic pumps;
- centrifugal pumps;
- positive displacement pumps;
- bailing (provided the bailer is gently lowered into ground water)

The method used must minimize the agitation of formation water entering the well during the purging process. A minimum of five well volumes are to be removed, or the well is to be purged until the physical parameters of pH and conductivity stabilize within $\pm 10\%$ difference and temperature within $\pm 1\%$ for three consecutive readings. These physical parameters are to be measured after removing each well volume. The total water volume removed and field measurements are to be included in the assessment report.

If at any time during the purging process water levels in the well indicate that it is in danger of being purged dry, purging is to be halted. The failed purging attempt must be included in the investigation report, and for the current and any future sampling events the well is to be purged according to Section 4.5.3.2, below.

4.5.3.2 Monitoring Wells in Fine Grained Materials (clays, silts, or very fine sands)

Wells in which 100% of the screened interval consists of fine-grained sediments will be considered to be low-yield wells. Also included in this category are wells containing a mixture of fine- and coarse-grained sediments within the screened interval, if designated by the Department or if a purging attempt has indicated that there is insufficient recharge to allow purging in accordance with Section 4.5.3.1.

Low-yield wells, if the screened interval intersects the ground water table, are at risk of being purged dry and are not to be purged at all. Low-yield wells screened completely below the ground water table are to be purged of stagnant water only to the top of the screen. The method used must minimize the agitation of formation water entering the well and any fine-grained material within the well. The preferable method is to use low-flow pumps.

4.5.4 – Abandonment of Monitoring Wells

When monitoring wells are no longer needed for the site investigation or remedial activities, they must be abandoned in accordance with DHHS Title 178. For sites eligible for reimbursement under Title 200, a work plan and cost estimate must be submitted and the Department's approval received before abandonment may take place.

4.5.4.1 Request to Retain Monitoring Wells for Subsequent Use

Once the Department determines that monitoring wells are no longer needed at a site, the responsible party or other property owner may request to retain one or more of the wells for their subsequent use. The request must be submitted in writing, identifying the well(s) in question by identification number and by designation on a copy of the site map and specifying the intended future use of the well(s). The Department will consider the request, but under no circumstances can a well be retained for a use that would constitute a new Point of Exposure resulting in a change to the site's RBSLs or SSTLs and leading to the need for additional remedial actions. If approved for well retention is granted by the Department, the Department of Natural Resources must be notified to transfer formal ownership of the well(s) to the new owner. A copy of the revised registration must be provided to the Department. The new owner will assume full responsibility for the security, maintenance, and eventual abandonment of the well(s).

4.6 – FREE PRODUCT ON GROUND WATER

Free product will be defined as measurable (≥ 0.01 feet) petroleum product thickness that is present as a non-aqueous-phase liquid (but will not include a product sheen).

4.6.1 – Discovery of Free Product

If free product is detected on ground water during the site investigation, the Department must be notified, and additional actions are required depending on the site conditions:

- If the depth to ground water is ≤ 20 feet below ground level (BGL) and subsurface structures (e.g., storm or sanitary sewers, buildings with basements or crawl spaces) are present, a vapor assessment must be conducted according to Section 4.7.4. The results are to be reported as specified in Table 2-1.
- If the depth to ground water is greater than 20 feet BGL or no subsurface structures are present, the Department must be notified by the next business day. The site investigation can continue as planned with the exception that no ground water samples should be collected for laboratory analysis from monitoring wells containing a measurable thickness of free product.

The free product response process is depicted as a flow chart in Figure 4-1.

Upon notification of the presence of free product, the Department may amend the Tier 1 or Tier 2 site assessment to include a subsurface investigation to assess the extent of the free product plume. The minimum data requirements for a free product assessment are provided in the following section.

Figure 4-1. Free Product Response Process

4.6.2 – Minimum Free Product Assessment Data Requirements

- Items 1 - 5 of Section 5.1 (covering historical information, land use assessment, identification of petroleum product released and appropriate COCs, location and number of source areas, and potential POE information).
- Subsurface soil and surface soil (where applicable) samples must be collected, for analysis of the appropriate COCs. The actual number of samples to be analyzed is described in Section 5.2.1 (for subsurface soils) and Section 5.2.2 (for surface soils).
- The extent and magnitude of free product must be assessed by placing monitoring wells outward from the source areas in such a manner as to allow for the full lateral delineation of the free product plume and by measurement of apparent free product thickness in the wells. Results are to be depicted on a Free Product Map as detailed in Section 4.3.1.4.
- For sites with a depth to ground water of 20 feet or less, on-site subsurface structures (including but not limited to storm and sanitary sewer lines, utility conduits, and basements) must be assessed for the presence of vapors. Subsurface utilities must be assessed for the presence of explosive vapors. Buildings directly above the free product plume must be assessed for the presence of **any** petroleum vapors using the procedure provided in Section 4.7.4.
- In instances where a water supply well is impacted or may be threatened, installation and ground water sampling of a sentinel monitoring well(s) placed between the water supply well and the free product plume may be required by the PRS Project Manager. Several sentinel monitoring wells may be required and may be screened at varying depths.

4.7 – GENERAL SAMPLING REQUIREMENTS

4.7.1 – General Subsurface Advancement Methods

Methods of accessing subsurface soils and ground water are discussed in Sections 4.5.1.2 through 4.5.1.4. Geoprobe or other direct push technologies are not allowed for Tier 1 investigations and may be applicable for only some Tier 2 pathways.

4.7.2 – Soil Sample Collection Methods

Methods to be used in the sample collection of subsurface soils are as follows:

4.7.2.1 Sampling of Surface Soils

Surface and near-surface soils represent a threat of dermal exposure or inhalation or ingestion of particulates. The appropriate sampling strategy depends on the source of the release and thus, the expected nature of the contamination:

1. For releases originating from **underground storage tank systems or buried piping** where surface soil contamination is present, surface soil samples are to be obtained from source-area borings at a depth between 0.5 and 3 feet BGL using split-barrel or thin-walled tubes as described in ASTM D 1586-84 Method for Penetration Test and Split-Barrel Sampling of Soils and ASTM D 1587-83 Practice for Thin-Walled Tube Sampling of Soils. Field screening of a portion of the sample is to be performed in accordance with Section 4.7.2.3. The portion of the cored sample used for laboratory analysis is to be collected in accordance with Section 4.7.2.4.
2. For **releases upon the surface of the land**, where contaminated surface soils are still present, one sample must be collected for laboratory analysis from each source area of 100 square feet or less, with a further sample collected for every additional 400 square feet of affected area (see Figure 3-1b). Samples must be collected from a depth between 0.5 and 3 feet BGL at points where the highest levels of contamination are measured, evident, or suspected within the affected area. In order to determine the area of contamination, field screening must be performed on a portion of the sample in accordance with Section 4.7.2.3 and another portion submitted for laboratory analysis in accordance with Section 4.7.2.4.

4.7.2.2 Continuous Sampling

Since one of the objectives in the sampling of a source area is to collect samples from what are suspected or perceived as the most contaminated portions of the boring, continuous sampling of all borings used to characterize soil contamination is required. Soil samples are to be collected using split-barrel or thin-walled tubes as specified in Section 4.7.2.1, Item 1.

All soil samples will be split into at least two different portions or aliquots at the time of sampling. One portion will be used for headspace screening and characterization. The other portion(s) will be transferred to and sealed in an appropriately prepared sample jar for possible laboratory analysis, and immediately placed on ice.

Tier 1 borings: Continuous sampling is required at all boring/monitoring well locations in identified source areas. Continuous sampling is generally not required at any non-source boring/monitoring well location. However, if evidence of contamination (field screening, visual/olfactory) is detected in the vadose zone during non-source-area drilling, continuous sampling is required for the remainder of that boring and samples for laboratory analysis must be collected as for a known source-area boring.

Tier 2 borings: Continuous sampling will be required at downgradient and cross gradient locations to characterize the geology across the site in addition to the borings used to characterize soil contamination. Where a boring is continuously sampled solely for the purposes of describing the site geology, analytical samples are not required. This information will be used to construct geologic cross sections parallel and perpendicular to the ground water flow direction. However, if evidence of contamination (field screening, visual/olfactory) is detected in the vadose zone during non-source-area drilling, continuous sampling is required for the remainder of that boring and samples for laboratory analysis must be collected as for a known source-area boring.

4.7.2.3 Field Screening

For consistency, only static headspace analysis for field screening of soil samples is to be used. Static headspace analysis must be performed using the following method:

1. Place the soil sample in a clean, wide-mouth glass jar with a screw-on, airtight lid. (Plastic bags are not allowed for field screening and laboratory analysis.)
2. Gently fill the jar one-half full with the soil sample.
3. Cover the mouth of the jar immediately with aluminum foil and secure the lid.
4. Place the jar in an environment above 60° F for 30 minutes.
5. Measure the contaminant level by removing the lid and puncturing the foil immediately with the instrument probe.
6. Record the highest level that the instrument registers.

Acceptable field instruments are Photoionization Detectors (PIDs), Flame Ionization Detectors (FIDs), and portable Gas Chromatographs (GCs). At a minimum, all field instruments are to be cleaned prior to use at each site and calibrated immediately before use and at regular intervals during use in accordance with the manufacturer's specifications.

4.7.2.4 Soil Sample Collection and Transport for Laboratory Analysis

The following procedure is to be used in collecting laboratory samples:

1. Prior to sampling, contact the laboratory for specific container requirements.
2. Quickly and gently place soil samples (do not compact soil) in the sample container, leaving as little headspace as possible.
3. Immediately seal containers with air-tight, Teflon-lined, screw-on lids.

In an effort to limit the loss of volatile organics during sample collection and shipping, a portion of each soil sample interval must be delivered to an appropriately prepared sample jar for possible laboratory analysis and immediately placed on ice. Once all field analyses have been performed, the appropriate number of samples, corresponding to the locations of highest contamination as documented by field screening, is to be submitted for laboratory analysis.

4.7.3 – Ground Water Sample Collection Methods

Any method used to collect ground water samples must minimize agitation. Suction, airlift, inertial lift (Waterra ® or similar), or peristaltic pumps are not to be used to collect samples due to their agitative action. Acceptable sampling methods include the use of:

- gear-drive pumps
- helical rotor pumps
- pneumatic piston pumps (sealed drive gas)
- bladder pumps
- passive diffusion bag samplers (for wells totally screened below the water table where MTBE is not identified and a vertical gradient is not present in the aquifer)
- bailing (provided the bailer is gently lowered into ground water)
- Hydrosleeves®

Laboratory requirements for sample containers, methods of preservation, and sample holding times must be followed. These requirements may be COC-specific. The sampling method should always be included in workplans and investigation report narratives. Once the monitoring wells have been opened and allowed to equilibrate, wells are to be

sampled from least contaminated to most contaminated. Ground water samples are to be collected in the following order to minimize the loss of volatiles:

1. VOCs (BTEX, n-hexane, MTBE)
2. Total Extractable Hydrocarbons

4.7.4 – Air Sampling for Subsurface Structure Vapor Assessment

Initial vapor assessment of potentially impacted subsurface structures (e.g., on-site basements [including crawl spaces and similar structures] and on-site and proximate sanitary and storm sewers or utility conduits) is to be conducted using a photoionization detector (PID) or flame ionization detector (FID). If elevated levels of contamination are detected with the PID/FID, additional site screening is to be performed using a combustible gas indicator (CGI) or other explosimeter to determine the extent of the vapor impact. If explosive vapor concentrations are detected at a level >1% of the lower explosive limit (LEL) within a structure, as indicated by the explosimeter, the local fire department, State Fire Marshal's Office, and the Department must be contacted immediately as described in Table 2-1. These agencies will then determine the need for immediate mitigative actions. The location and depth of each structure showing evidence of vapor impact must be determined and included on the site map (Section 4.3.1.3).

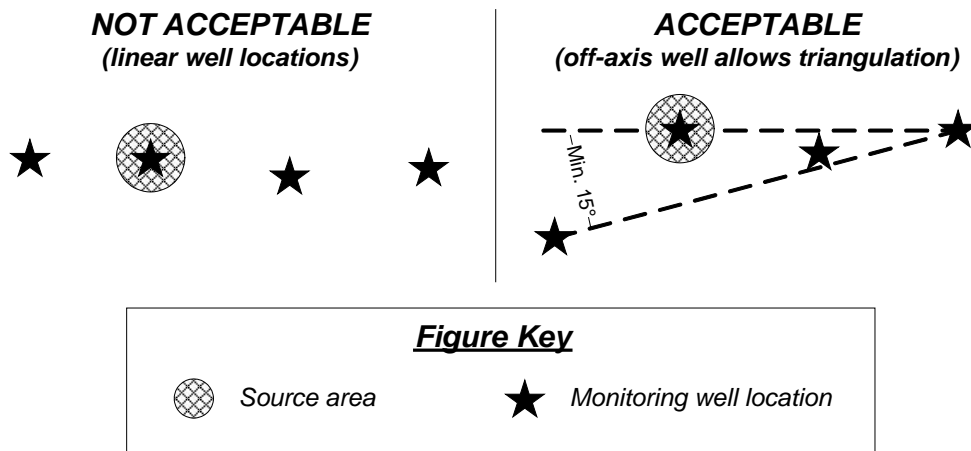

Table 2-1 provides a summary of notification requirements to be followed. If any vapor concentrations are detected within a building and do not represent an explosive hazard as described in the preceding paragraph, the Department must be contacted by the next business day. The Department will then determine what actions are needed in the immediate, short-term and long-term time frames to mitigate the vapor problem.

4.8 – SATURATED ZONE CHARACTERISTICS

4.8.1 – Ground Water Flow Direction

Accurate determination of the ground water flow direction at the site is a critical part of both the Tier 1 and Tier 2 investigations. Monitoring well locations must be selected to avoid a linear or near-linear arrangement which might result in an erroneous concept of the flow direction. At least one well must be sited 15 degrees or more off-axis in order to allow for adequate triangulation and determination of a representative ground water flow direction. See Figure 4-2 for examples.

Figure 4-2. Well Placement for Determining Ground Water Flow Direction

The linear well arrangement in the first example can result in an ambiguous ground water flow direction. Placing at least one well off-axis as in the second example allows for triangulation and a more reliable determination of the ground water flow direction.

4.8.2 – Hydraulic Conductivity

Site-specific values for hydraulic conductivity based on slug or pump tests will not be required for Tier 1 and Tier 2 investigations. Hydraulic conductivity values are to be selected from the values provided in Table 4-3, based on sediment type and other descriptive features (e.g., sorting) from the boring logs.

Table 4-3. Estimated Hydraulic Conductivity (K) Values from Particle Size Descriptions

Grain Size	Degree of Sorting			Silt Content		
	Poor	Moderate	Well	Slight	Moderate	Very
Clay and Silt						
Clay	0.7	----	----	----	----	----
Clay, silty	1.3	----	----	----	----	----
Silt, clayey	2.7	----	----	----	----	----
Silt	6.7	----	----	----	----	----
Silt, sandy	10.7	----	----	----	----	----
Sand and Gravel						
Very fine sand	13.4	20.1	26.7	22.7	18.7	13.4
VF to F sand	26.7	26.7	----	24.1	20.1	13.4
VF to M sand	36.1	----	----	32.1	26.7	20.7
VF to C sand	48.1	----	----	40.1	30.7	24.1
VF to VC sand	58.8	----	----	50.8	40.1	29.4
VF sand to F gravel	76.2	----	----	66.8	52.1	38.1
VF sand to M gravel	98.9	----	----	80.2	65.5	49.5
VF sand to C gravel	128.3	----	----	107	85.6	64.2
Fine sand	26.7	40.1	53.5	33.4	26.7	20.1
F to M sand	53.5	66.8	----	48.1	39.4	30.1
F to C sand	57.5	----	----	53.5	42.8	32.1
F to VC sand	70.2	----	----	60.2	47.5	34.8
F sand to F gravel	88.2	----	----	73.5	58.8	44.1
F sand to M gravel	113.6	----	----	93.6	74.9	56.8
F sand to C gravel	145.1	----	----	107	86.9	72.2
Medium sand	66.8	80.2	93.6	63.5	51.5	40.1
M to C sand	73.5	93.6	----	72.2	57.5	42.1
M to VC sand	84.2	----	----	73.5	60.8	48.8
M sand to F gravel	103.6	----	----	83.6	68.2	52.1
M sand to M gravel	131	----	----	113.6	81.6	65.5
M sand to C gravel	164.4	----	----	133.7	108.3	82.2
Coarse sand	80.2	107	133.7	93.6	73.5	53.5
C to VC sand	93.6	133.7	----	93.6	74.9	56.8
C sand to F gravel	116.3	----	----	107	87.6	68.2
C sand to M gravel	147.1	----	----	113.6	93.6	73.5
C sand to C gravel	184.5	----	----	133.7	99.6	92.2
Very coarse sand	107	147.1	187.2	113.6	93.6	73.5
VC sand to F gravel	133.7	213.9	----	120.3	103.6	86.9
VC sand to M gravel	169.8	----	----	147.1	123	98.9
VC sand to C gravel	207.2	----	----	160.4	131.7	103.6
Gravel						
Fine gravel	160.4	213.9	267.4	160.4	140.4	107
F to M gravel	200.5	334.2	----	200.5	167.1	133.7
F to C gravel	244.7	----	----	234	189.2	144.4
Medium gravel	240.6	320.9	401.1	240.6	200.5	160.4
M to C gravel	294.1	467.9	----	294.1	242.6	190.5
Coarse gravel	334.2	467.9	601.6	334.2	284.1	234

All values are expressed in feet/day.

Source: DEQ Wellhead Protection Program (modified from Reed and Piskin, UNL-CSD)

4.8.3 – Hydraulic Gradient

The hydraulic gradient is to be determined by taking the difference in hydraulic head (in feet) between two or more wells screened in the same aquifer aligned in the direction of ground water flow and dividing by the distance (in feet) between the wells.

4.8.4 – Depth to Ground Water

The depth to ground water is one of the factors used to determine the appropriate RBSLs and calculation of SSTLs for the following exposure pathways:

- Soil leaching to ground water
- Intrusion of vapors to structure from contaminated ground water

For estimating RBSLs and SSTLs for the intrusion of vapors from contaminated ground water pathway, depth to ground water must be measured from below the bottom of a basement or crawl space, if present, or from ground surface, if no basement or crawl space is present.

The thickness of the vadose zone is based on the depth below grade at which the ground water interface is encountered. Depth to ground water information must be collected as follows:

1. Reference elevations to a local or United States Geological Survey (USGS) benchmark. A local benchmark is any arbitrary, permanent, nearby feature or structure to which all subsequent elevation can be referenced over a number of years. The location of the selected benchmark must be identified on the site maps (Section 4.3.1.3). Measure the depth to water to within 0.01 foot from the top of the monitoring well casing.
2. Place a permanent mark on the well casing so all subsequent sampling events are measured from the same spot.
3. Take measurements with an interface probe or electronic measure tape (E-line).

Static water levels are dependent on site-specific conditions, including well construction, which could lead to aberrant ground water level readings. The use of stick-up wellhead protectors and vented caps may greatly reduce the time needed to obtain true static water levels; however, vented caps are not to be used when the well is constructed in an area prone to flooding or surface drainage. All wells should be opened and adequate time allowed for water levels to stabilize prior to taking water level measurements. All water levels for the development of ground water contour maps are to be obtained during a single measurement event. All water level measurements and the time (i.e., date, hour, minutes) they were taken are to be recorded and submitted as part of the assessment report.

4.8.5 – Ground Water Table Variations

Seasonal variations in water table depth and flow direction should be included, if known. This information may be gathered as either: 1) site specific data or 2) “areal” information based on past investigation and monitoring at other nearby release sites.

4.8.6 – Porosity

For Tier 1, values for soil porosity (symbolized as “n”) are either of two default values: sands/gravels (n = 0.30) or silts/clays (n = 0.35). The default porosity is determined based on the predominant sediment type in which a documented or potential POE (e.g., well screen, basement) is situated.

For Tier 2, porosity values are to be selected from the values provided in Table 6-2 (see Section 6.2.1).

4.8.7 – Calculated Ground Water Flow Velocity

For the Tier 1 and Tier 2 investigations, the general ground water flow velocity is calculated in the report forms using the following equation:

$$\frac{K \times i}{n}$$

Where: K is the hydraulic conductivity in feet per day
 i is the hydraulic gradient (dimensionless)
 n is the porosity of the saturated sediments

4.9 – QUALITY ASSURANCE/QUALITY CONTROL CONSIDERATIONS

Soil and ground water samples should be collected carefully and consistently at all times. Soil for samples should be handled quickly and with as little disturbance as possible, and all water samples for volatile analysis should be checked for bubbles after sealing the sample container. If any bubbles are present, a new sample should be collected. To improve the overall quality and consistency of the data collected, the Department also requires that certain quality assurance/quality control (QA/QC) actions be taken during the Tier 1 and Tier 2 investigations. A QA/QC program ensures that the quality of the data generated is sufficiently reliable for the RBCA process and that the results are representative, accurate, precise and comparable.

If the following QA/QC samples are not collected and the results documented in the report, the chain-of-custody is broken, sample holding times are exceeded, or any other event occurs that may cast doubt on the quality of the data, the samples must be recollected. For Title 200 eligible releases, only costs associated with usable data can be eligible for reimbursement. If samples must be recollected due to a QA/QC issue, the costs associated with the first sampling event will most likely be ineligible for reimbursement.

QA/QC requirements and considerations apply to Tier 1 and Tier 2 investigations as well as any other sampling required by the Department, and include the following:

4.9.1 – “Blind” Duplicate Samples

One duplicate sample is required for every five monitoring wells or points sampled for ground water or soil gas. This means that one duplicate sample is required for five wells or less, two duplicates for six to ten wells, etc. The duplicate samples are to be collected from monitoring wells known or suspected to be contaminated. Sampling bottles must not be labeled as “duplicate.” Duplicate samples are to be collected and analyzed for the same COCs as the original sample. Results must be provided in the designated Report Form.

4.9.2 – Field Blanks

The purpose of field blanks is to assess the potential contribution of airborne contaminants to ground water samples. Ample field blanks are to be prepared. The sample container and preservation requirements are to comply with the laboratory requirements for the specific contaminants. Field blanks are to be analyzed for all applicable COCs for which ground water samples are being collected, except for TEH or specific naphthalene samples. One field blank must be collected at the beginning of each day’s sampling. One additional field blank is required whenever site conditions (e.g., when moving work efforts from a low-activity or low-traffic area like a residential area to a high-activity or high-traffic area like along a highway on the same site) and/or weather conditions change.

During the ground water monitoring well sampling event, the field blank must be opened and exposed to ambient conditions for a period equal to the time from when the sample container is opened or the bailer or sampling pump first contains the actual sample (whichever is first) to when the sample vial/jar is closed, since this is when the ground water

sample and the interior of the sample container are exposed to the atmosphere. The amount of time the field blank was exposed to ambient conditions should be recorded on the QA/QC form. After closing the blank VOC vials, they should be inspected for bubbles and any problems noted on the chain-of-custody only. Results should be provided in the designated Report Form.

4.9.3 – Trip Blanks

The purpose of the trip blank is to assess if sample bottle preparation, sample shipment, and laboratory handling and storage practices impact sample integrity. The blank water sample(s) must be prepared by the laboratory or in the office prior to traveling to the site for the sampling event and must remain untouched while in the shipping container. The trip blank must be preserved as required by the laboratory and maintained under the same chain-of-custody as the other samples. One trip blank is required for each cooler used during the sampling event. Trip blanks are to be analyzed for all applicable COCs for which ground water samples are being collected, except that no trip blanks are required for TEH or specific naphthalene samples. Results should be provided in the designated Report Form.

4.9.4 – Temperature Blanks / Thermometers

The purpose of a temperature blank is to ensure that samples have been maintained at a temperature of 4°C from the time of collection through their delivery to the laboratory. Temperature blanks may be provided by the laboratory or the temperature may be measured in the field using a laboratory-grade thermometer prior to sealing the shipping container. If the samples are not delivered at 4°C ($\pm 2^\circ\text{C}$), the laboratory must note this on the chain-of-custody. Consequently, the Department may consider the data quality questionable. One temperature blank is required for each shipping container. Results should be provided in the designated Report Form.

4.9.5 – QA/QC Documents

The chain-of-custody record is to be started when the trip blank(s) are placed into the sample cooler. A copy of the chain-of-custody is to accompany each sampling event through delivery of the samples to laboratory. A copy of the chain-of-custody record is to be included in the investigation report. All samples must be maintained under the chain-of-custody. If the chain-of-custody is broken, samples must be recollected after informing the Department of the event. A site investigation report cannot be considered complete by the Department when the chain-of-custody has been broken.

Any reports which include laboratory analytical data must also contain the spiked-sample analysis results and chromatograms for all samples.

4.9.6 – Field Instrumentation Calibration

Field instruments are to be calibrated immediately before use and at regular intervals during use according to the manufacturer's specifications. Calibration intervals are to be included in the narrative section of the final report.

4.9.7 – Decontamination of Sampling Equipment

In addition to ensuring field instruments are cleaned and properly maintained, new or laboratory-cleaned sample containers must be used for the collection of each soil or ground water sample. In addition, the following decontamination requirements apply to ancillary sampling equipment.

4.9.7.1 Soil Samples

The sample collection device (e.g., split-barrel or thin-walled tube), and any other instrument contacting the sample, must be decontaminated between each sample. At a minimum, decontamination is accomplished by washing the device with a laboratory-grade detergent (e.g., Alconox, Detergent 8) after removing all loose material, followed by two clean water rinses (final rinse of deionized water). The soil sample must be placed in a new or laboratory cleaned sample container. Auger stems are to be decontaminated (e.g., steamed-cleaned, scrubbed with a laboratory grade detergent) before drilling a new borehole.

4.9.7.2 Ground Water Samples

The order of sampling is to be from the least contaminated to most contaminated well (i.e., source areas). Any device used to purge (where applicable) or sample a monitoring well must be appropriately decontaminated prior to introduction into the well. At a minimum, such decontamination is accomplished by washing the device with a laboratory-grade detergent (e.g., Alconox, Detergent 8) after removing all loose material, followed by two clean water rinses (final rinse of deionized water). If a bailer is to be used to collect a water sample, it must be a new, disposable bailer or a laboratory cleaned, reusable bailer. New bailer line must be used for each well (unless Teflon-coated, allowing for decontamination). The water sample must be placed in a new or laboratory cleaned sample container.

Refer to ASTM Standard D 5088-90 Standard Practice for Decontamination of Field Equipment Used at Nonradioactive Waste Sites for additional information concerning the decontamination of drilling and sampling equipment exposed to other contaminants.

4.10 – DOCUMENTATION OF NEBRASKA RBCA INVESTIGATION

The information gathered for the RBCA investigation is to be documented and recorded on the forms provided by the Department for the particular RBCA Tier assessment. Examples of these Report Forms can be found in Appendix B (Tier 1) and Appendix C (Tier 2). Copies of these forms in Microsoft Excel format may be downloaded from the Department's web page (www.deq.state.ne.us; see Publications/Forms) or are available on request by contacting a PRS Project Manager.

In addition to the Report Forms cited above, the following additional information is to be provided in the general formats discussed below.

4.10.1 – Maps

Maps as discussed in Section 4.3.1 are to be included in the investigation report.

4.10.2 – Boring/Monitoring Well Data

4.10.2.1 Licensing and Registration

Companies and individuals engaged in the installation, servicing, and sampling of monitoring or water wells in Nebraska are required to hold a license for that purpose, issued by the Nebraska Department of Health and Human Services (DHHS) Water Well Standards and Contractors' Licensing Program (see Appendix F). The requirements are contained in DHHS Title 178, which also sets forth the acceptable standards for well installation and construction.

Names and license numbers of personnel or subcontractors involved in installing or sampling wells during the investigation must be recorded on the appropriate Tier 1 or Tier 2 Report Form, or included as part of any remediation or monitoring report.

If a regulatory variance from the Title 178 regulations is desired, the PRS Project Manager must first be contacted and agree to the proposal. The variance must be obtained from DHHS prior to conducting the field work and a copy of the variance must be submitted with the workplan and report.

All monitoring wells must be registered with the Nebraska Department of Natural Resources (DNR). Contact information is available in Appendix F.

4.10.2.2 Boring Logs

Boring logs (or the results obtained from direct push technologies or other approved methods) are to include, at a minimum, the following information:

- a) Consultant company name.
- b) Project name.
- c) Drilling contractor name (if other than consultant).
- d) Names of personnel present from the consulting company and drilling contractor.
- e) DHHS license numbers of all personnel involved in installing the boring.
- f) Date and time drilling started and ended.
- g) Boring identification number.
- h) Surface elevation.
- i) Boring location.
- j) Drilling method.
- k) Sediment description and classification (provide system used).
- l) Sample collection depth intervals.
- m) Field screening analysis results.
- n) Total depth of boring.
- o) Depth to water at time of drilling. Include date and time of measurement.
- p) Stabilized depth to water. Include date and time of measurement.
- q) Indicate if the boring was abandoned or completed as a permanent monitoring well.

4.10.2.3 Ground Water Monitoring Wells

Construction details for monitoring wells are to include the following minimum information:

- a) Well identification number.
- b) Installation date.
- c) Top of casing elevation.
- d) Ground level elevation.
- e) Screen slot size.
- f) Casing and screen material.
- g) Length of screen (should never be >10 feet unless approved).
- h) Screened interval depths.
- i) Stabilized water level.
- j) Gravel-pack material and interval.
- k) Bentonite seal interval(s).
- l) Bottom of well elevation.
- m) Grout type and interval(s).
- n) Consultant company name.
- o) Drilling contractor name (if other than consultant).
- p) Names of personnel present from the consulting company and drilling contractor.
- q) DHHS license numbers of all personnel involved in installing the monitoring well.
- r) DNR registration number, if available at the time of the report.
- s) Lapsed development time.

4.10.2.4 Soil Vapor Monitoring Wells

Wells constructed as permanent vapor monitoring points that do not contact the water table are not regulated under Title 178 at the time of this writing. This situation may change in the near future, and the Department recommends consulting the DHHS if vapor monitoring wells are planned as part of an investigation. Such wells do, however, have to be registered with the Department of Natural Resources as soil vapor monitoring wells under the "Other" category.

If soil vapor monitoring wells are installed, the following minimum information must be provided in the report:

- a) Well identification number.
- b) Installation date.
- c) Screen slot size.
- d) Casing and screen material.
- e) Length of screen.

- f) Screened interval depths.
- g) Bottom of well elevation.
- h) Seal type and interval(s).
- i) Consultant company name.
- j) Drilling contractor name (if other than consultant).
- k) Names of personnel present from the consulting company and drilling contractor.
- l) DNR registration number, if available at the time of the report.

4.10.3 – Cross Sections

Cross sections are to be constructed using the results of the subsurface borings and must provide an understanding of the subsurface geology and clearly indicate known and inferred areas of contamination. Cross sections are required as follows:

- **Tier 1 Investigation** – No cross sections necessary.
- **Tier 2 Investigation** – A minimum of two views, including one parallel to and one perpendicular to the ground water flow direction. The views should intersect the source area(s).

4.10.4 – Sampling Data

The following information, at a minimum, is to be noted in or provided as an appendix to the final report:

- Analytical method and version employed,
- All laboratory analysis sheets produced by the analytical laboratory, including chromatograms, and
- All chain-of-custody sheets generated.

Laboratory data may be provided in electronic form as described in Section 4.10.5.2, provided that a printed summary table is included in the report.

4.10.5 – Electronic Report Submittal

4.10.5.1 Reports via E-mail

All Tier 1 and Tier 2 investigation reports must be submitted in paper form. In some circumstances such as emergencies and urgent situations, it may be acceptable to submit certain data, photographs, or other information by e-mail prior to the submittal of the printed report. The PRS Project Manager must be contacted in advance for approval before the information is submitted.

4.10.5.2 Reports on CD

To conserve paper and reduce the physical size of the report and to save printing and postage expenses, the following supporting information may be submitted in electronic form on a standard CD-R instead of being printed:

- Lab analytical data (provided that a printed summary table is included in the report).
- Pump test data.
- SVE, AS, or other pilot test data.
- Well registration and abandonment forms.

All other information, such as boring logs, well construction diagrams, maps, or photos, must be included in its entirety in the printed report.

Such electronic submittal is not a requirement. It is an option that is available, to be used at the consultant's discretion. Should any of the above information be submitted on CD, the following requirements apply:

- The CD must be labeled with the site name, DEQ spill number, DEQ IIS number, and report name and date. It must also be titled as an Appendix to the report.
- A table of contents must be included in the Appendix's position in the printed report, listing each of the files included on the CD.
- Files are to be in PDF format.
- Appropriate sections of the printed report are to contain a brief summary of the information, as well as references directing the reader to the CD for complete details. For example: *"Pilot test results indicate that SVE would be feasible at the site, with a minimum estimated radius of influence of 25 feet. Refer to the file SVE_TEST.PDF in Appendix E for full details."* If laboratory analytical results are provided on CD, a table summarizing the results for every well sampled must be included in the printed report.

The CD may be submitted as an unattached appendix or bound into the printed report.

This page intentionally left blank

SECTION 5.0 – TIER 1 SITE INVESTIGATION

Prior to initiating a Tier 1 site investigation, the Department requires that a workplan, complete with the proposed sampling locations, and cost estimate be submitted for review for Title 200 eligible sites. A workplan, without a cost estimate, is required for sites not eligible for Title 200 reimbursement. Copies of any variances from regulations obtained from the Department or any other agency for environmental work related to the Tier 1 investigation must be included with the workplan. Any proposed changes from the methods presented in this document must be highlighted and explained. Access agreements should be secured with property owners for all planned and prospective drilling locations prior to mobilization for fieldwork. The RP is to proceed with the Tier 1 site investigation within the established time schedule once the Department's approval letter is received.

The following provides guidance regarding the information required to complete the requirements of a Tier 1 investigation. The Minimum Site Assessment Data Requirements section below provides a general outline of the required information. Detailed requirements for specific tasks in the site investigation are referenced as needed.

Direct push technologies are not to be used to collect data for a Tier 1 investigation. Title 178 does not currently allow the use of direct push to install the permanent monitoring wells that are required as part of the Tier 1 investigation.

5.1 – MINIMUM TIER 1 SITE ASSESSMENT DATA REQUIREMENTS

The minimum investigation data needs for a petroleum release Tier 1 site assessment are as follows:

1. Historical information, particularly of past releases and the results of any associated investigation(s), if any.
2. Identification, location, and number of source areas to be investigated. See Section 3.2.2.
3. Identification of petroleum product(s) released to the environment (for determining appropriate COCs; see Section 4.2).
4. An assessment of land use in the area of the release site. See Section 4.4.
5. Information regarding:
 - The location and distance of water supply wells as provided in Section 4.4.3;
 - The use of the water produced by each well and the potential for human access to it (faucets, sprinklers, etc.);
 - The location of permanent surface water bodies within 1000 feet of the source area(s), as described in Section 4.4.5; and,
 - The location of all structures, including all buildings (and depths of any associated basements) and subsurface utilities within 200 feet of the source area(s), as outlined in Section 4.4.4. It is especially important to ascertain if the buildings have subsurface structures (e.g., basements, crawl spaces, or cellars).

NOTE: It is only since 1993 that domestic water wells had to be registered with the State. Many domestic wells will not appear in the Nebraska Department of Natural Resources registered well database (see Appendix F). Consequently, it is very important that a house-to-house survey be conducted to determine if any domestic drinking water wells are located within 1000 feet of the source area(s). In addition, local water/utility superintendents are a useful source of such information.

6. The presence of free phase petroleum product on ground water should be determined as described under Section 4.6.

NOTE: When free product is encountered on ground water, certain site investigation requirements for Tier 1 ground water sampling may be suspended until all free product issues have been resolved. In such an instance, the RP is still responsible for completing any unsuspended Tier 1 requirements as well as performing all actions and providing all information described in the **FREE PRODUCT ON GROUND WATER section (Section 4.6) by the Department's established compliance date.**

7. Soil and ground water samples must be collected for analysis of the appropriate COCs associated with the petroleum product(s) released to determine the on-site COC concentrations. Specific information regarding COCs and appropriate analytical methods are found in Section 4.2 and Table 4-1.

8. The actual number of samples to be obtained for laboratory analysis of the COCs is provided in Sections 5.2 (for soils) and 5.3 (for ground water).
9. An evaluation of vertical migration of the dissolved plume must be made where a water supply well may be of sufficient or suspected proximity and/or pumping capacity to influence the dissolved product plume. At least one deeper monitoring well may be required for sites with a drinking water well located within 250 feet of the release source area (Section 5.3).
10. The depth to ground water and its flow direction must be established, and the applicable saturated zone parameters (hydraulic conductivity, porosity and gradient) must be determined in order to calculate ground water flow velocity. See Section 4.8.
11. The names and addresses of ground water users and landowners within 500 feet of the site must be provided if the location is in a rural or non-incorporated community setting.

5.2 – NUMBER OF SOIL SAMPLES

All source area borings are to be sampled as described in this section. In addition, if contaminated soils are discovered in the vadose zone while drilling outside of known source areas, the well is to be continuously sampled from that point and soil samples collected using the same guidelines.

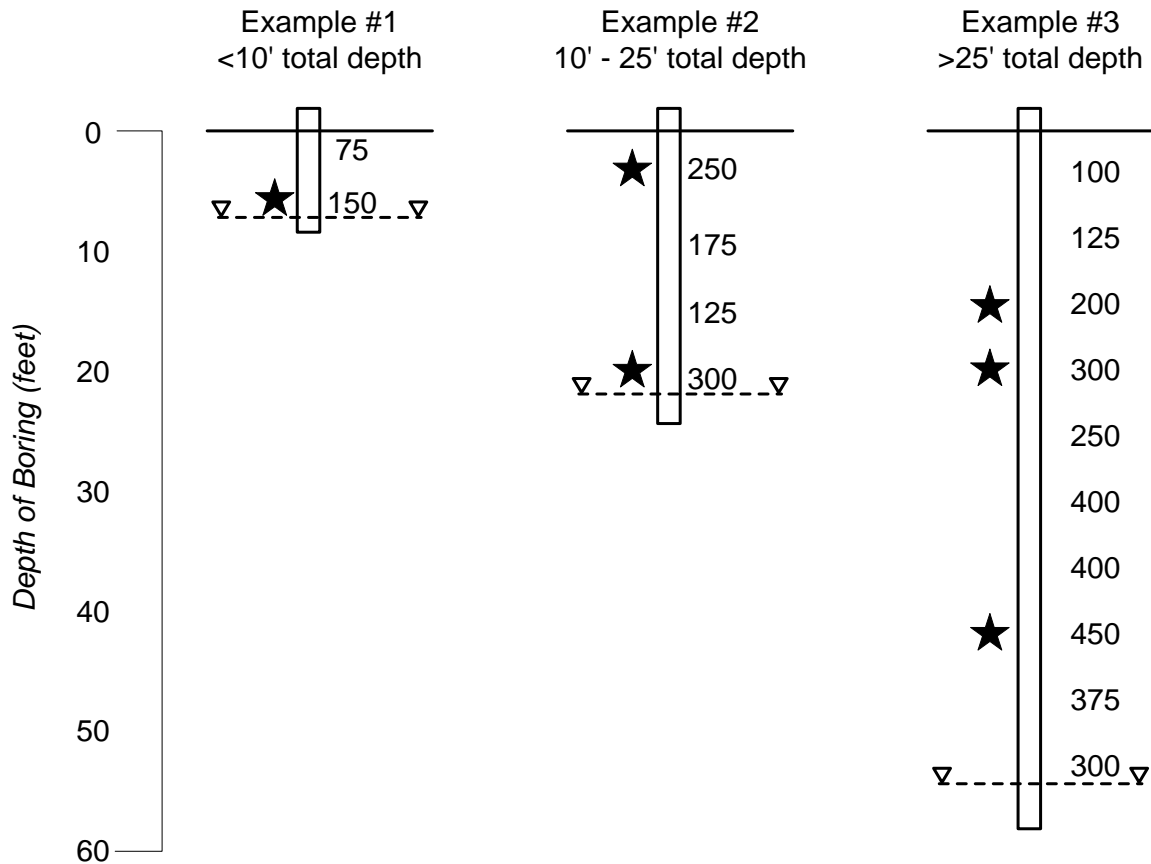

5.2.1 – Subsurface Soils

One to three subsurface soil samples from the vadose zone are to be analyzed from each applicable source boring/monitoring well, depending on the depth to ground water.

- Where ground water is <10 feet BGL, only one soil sample is required at the point where the highest level of contamination is measured by field instrumentation.
- Where ground water is ≥ 10 feet, but ≤ 25 feet BGL, two subsurface soil samples must be collected at the points where the highest levels of contamination are measured by field instrumentation.
- Where ground water is >25 feet BGL, two or three soil samples must be collected. Two soil samples must be obtained within the initial 25 feet BGL. For borings extending deeper than 25 feet, one additional soil sample is required **if** field instrumentation readings indicate a concentration greater than those identified in the first 25 feet of the boring. See Figure 5-1.

Should auger refusal (or near refusal) occur at depth before encountering ground water, a soil sample is to be collected from the bottom of the boring for laboratory analysis and the results (with the collection depth) submitted in the Tier 1 investigation report. A decision concerning the use of an alternate drilling method will be made after the laboratory soil analysis results have been discussed with the Department.

Figure 5-1. Examples of Subsurface Soil Collection Points

This figure provides a visual explanation for determining the need to collect 2 or 3 subsurface soil samples from a boring. Factors involved in this decision are depth to ground water and relative degree of contamination with depth. Field instrument readings are on the right side of the borings. Ground water is indicated by the dashed lines. Approximate sampling depths are marked by the star symbols. Samples must always be collected from within the unsaturated zone, rather than at or below the ground water table. In cases where an indicated sampling point is at the water table (Borings #1 and #2 in this example), the sample should be collected from just above the saturated sediments.

For Example #1, the ground water depth is less than 10 feet BGL. A single soil sample is required from the point of highest observed contamination.

For Example #2, the depth to ground water is less than 25 feet BGL, but greater than 10 feet BGL. In this circumstance, two soil samples would be required, since both samples would be used to evaluate the soil leaching to ground water exposure pathway and the enclosed space inhalation from contaminated subsurface soils exposure pathway.

For Example #3, ground water is in excess of 25 feet BGL and there is indication of higher contaminant levels at depth as evidenced by the elevated field instrument readings. Under these circumstances, three soil samples would be necessary. The two samples taken within the top 25 feet of the borehole would be used to evaluate the enclosed space inhalation from contaminated subsurface soils exposure pathway. A third sample from a perceived point of higher gross contamination at depth would be needed to adequately evaluate the soil leaching to ground water pathway.

5.2.2 – Surface Soils

Surface soils are defined as those unsaturated materials located between 0 and 3 feet BGL. Where surface soil contamination is present (i.e., recognized from ground surface staining), soil samples are to be collected **within each** surface source area. For individual surface source areas of less than approximately 100 ft², one sample is to be collected.

For source areas that exceed approximately 100 square feet (100 ft²), one sample is required within the first 100 square feet, as well as one additional sample for every further 400 square feet of affected area, at different points of obvious contamination. Examples are provided in Figure 3-1. The surface soil sample(s) must be collected at points where the highest level of contamination is measured, evident or suspected. The Department will assess the need for additional surface soil sampling during its review. Surface soil samples are to be obtained from a depth between 0.5 and 3 feet BGL.

5.3 – NUMBER OF GROUND WATER SAMPLES

The actual number of samples to be obtained for laboratory analysis is based on the following:

- One ground water sample is to be collected from a single monitoring well located upgradient of the source area(s) to establish background water quality.
- One ground water sample is collected from **each** source area.
- One ground water sample is to be collected from a minimum of one monitoring well located downgradient of the source area where petroleum contamination of the greatest concentration is suspected.
- If a downgradient recharge area is present, or a water supply well is located within 250 feet of the site and may be of sufficient pumping capacity to influence the dissolved product plume, at least one sample is to be collected at depth to address the possibility of vertical contaminant migration. The monitoring well is to be located between the source and the well or recharge area. If more than one such POE is present (or depending on the site geology and the screened interval of the threatened well) multiple monitoring wells may be necessary. The depth of the screened interval of the well(s) must be presented in the workplan.

5.4 – TIER 1 WAIVER OF GROUND WATER SAMPLING

Drilling to and sampling of ground water may be waived if **all** the following conditions are met:

1. All potential source areas identified in the workplan are investigated.
2. Clear evidence from field screening analyses and other field observations indicates the probability or likelihood that contamination has not migrated from the source through the entire thickness of the vadose zone. (That is, field screening no longer detects contamination in the vadose zone.)
3. The unsaturated zone interval between the point where contamination is no longer detectable with field instrumentation and the estimated depth of ground water at the site (based on regional information or past investigations in the area) is greater than 25 feet.
4. Two subsurface soil samples for laboratory analysis are collected from each boring: 1) at a minimum of five feet below the last indication of contamination and 2) at a minimum of 10 feet below the bottom of the previous sample interval. These two samples are in addition to the subsurface soil samples collected at the suspected points of highest contamination as described in Section 5.2.1.

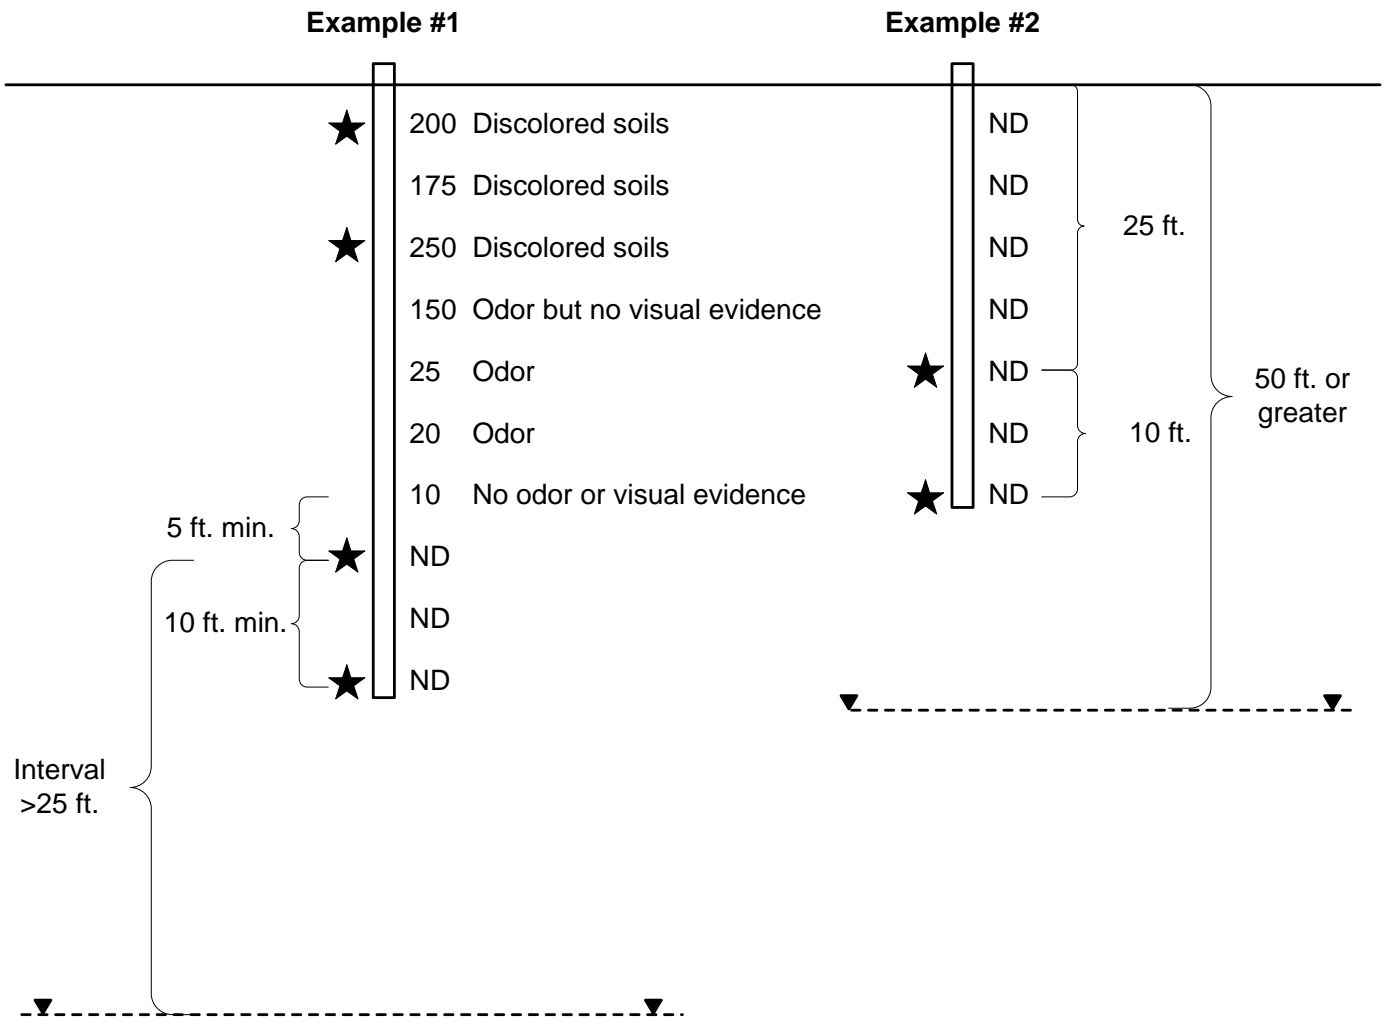

The ground water sampling waiver may also apply to source area borings that do not encounter any soil contamination. Soil samples are required at 25 feet and 35 feet BGL, and the anticipated depth to ground water must be 50 feet or greater.

Figure 5-2 provides a visual explanation of these sampling requirements. Documentation that supports the contention that ground water is at substantial depth (i.e., information from regional ground water maps, past environmental reports) must be provided in the investigation report.

If multiple source areas are present, the possibility of ground water sampling waiver is considered at each independently. In cases where at least one but not all source areas fulfill the waiver requirements, the PRS Project Manager should be contacted to discuss appropriate locations for installing the remaining non-source-area monitoring wells.

Should auger refusal (or near refusal) occur at depth before encountering ground water, a soil sample is to be collected from the bottom of the boring for laboratory analysis and the results (with the collection depth) submitted in the Tier 1 investigation report. A decision concerning the use of an alternate drilling method will be made after the laboratory soil analysis results have been discussed with the Department.

Figure 5-2. Conditions for Discontinuing Borehole to Ground Water

This idealized figure (not to scale) illustrates the conditions under which drilling through a source area may be discontinued without completing the boring to ground water during a RBCA Tier 1 investigation. Approximate sampling locations in the above examples are indicated by the star symbols.

Source Area #1: Visual, olfactory and field instrument evidence indicates no contamination is present at a point that is greater than 25 feet above the assumed level of ground water. In addition to the subsurface soil samples necessary to evaluate those exposure pathways associated with subsurface soils (see Figure 5-1), two more subsurface soil samples for laboratory analysis are required for each source area investigated to confirm the field observations. The first sample is to be collected at a point 5 feet below the last indication of contamination, and the second is to be collected at a minimum of 10 feet below the bottom of the previous sample interval.

Source Area #2: No evidence of contamination is present at any point in the boring, and the anticipated depth to ground water is at least 50 feet. Two soil samples for laboratory analysis are required, one at 25 feet BGL and the second at 35 feet BGL.

5.5 – TIER 1 REPORTING REQUIREMENTS

The Department has established a reporting format that the RP or their consultant is required to use for the submittal of the investigation results. The report format consists of Report Forms generated in Microsoft Excel for most of the required data. The Tier 1 Report Forms have been revised to incorporate the changes in this guidance document, and are located in the Department’s RBCA software package under the Excel file: *TIER_1_FORMS.xls*. The forms are presented in Appendix B. Copies of these forms in Microsoft Excel format may be downloaded from the Department’s website (www.deq.state.ne.us).

This page intentionally left blank

SECTION 6.0 – TIER 2 SITE INVESTIGATION

The Tier 2 investigation involves only those exposure pathways where contaminant levels exceeded the Tier 1 RBSLs. These pathways will be identified by the Department when the Tier 2 investigation is requested. Soil and/or ground water samples must be collected for analysis of the appropriate COCs associated with the petroleum product(s) released to determine the on-site COC concentrations. Specific information regarding COCs and appropriate analytical methods are found in Section 4.2 and Table 4-1.

Prior to initiating a Tier 2 site investigation, the Department requires that a workplan, complete with the proposed sampling locations, and cost estimate be submitted for review for Title 200 eligible sites. A workplan, without a cost estimate, is required for sites ineligible for Title 200. Copies of any variances from regulations obtained from the Department or any other agency for environmental work related to the Tier 2 investigation must be included with the workplan. Any proposed changes from the methods presented in this document must be highlighted and explained. The RP is to proceed with the Tier 2 site investigation within the established time schedule once the Department's approval letter is received.

Various methods can be used to collect the required Tier 2 data. Table 6-1 addresses the applicability of two of the most common techniques (auger drilling and direct push) for the various exposure pathways, as well as some alternative methods. Not all potentially applicable methods are listed in the table; the PRS Project Manager should be contacted to discuss the use of methods not specifically addressed in this guidance document.

Table 6-1. Common Data Collection Techniques for Tier 2 Investigations

Exposure Pathway	Conventional (Auger) Drilling Techniques	Direct Push Technologies (see NOTE below)	Other Methods (not inclusive)
Free Product delineation	Borings must be completed as permanent monitoring wells.	NOT ACCEPTABLE	
Ground Water Ingestion	YES	Sample collection only. Cannot be used to install monitoring wells.	
Soil Leaching to Ground Water	YES	YES	
Inhalation of Vapors from Ground Water	Acceptable for ground water sample collection.	Acceptable for ground water or vapor sample collection. Vapor samples must be analyzed in accordance with Section 6.3.1.	Hand-installed subfloor soil gas sampling points.
Inhalation of Vapors from Contaminated Subsurface Soil	Acceptable for soil sample collection.	Acceptable for soil or vapor sample collection. Vapor samples must be analyzed in accordance with Section 6.3.1.	Hand-installed subfloor soil gas sampling points.
Surface Soil Contamination	N/A – There are no separate Tier 2 SSTLs for this pathway. If the Tier 1 RBSLs are exceeded, remedial actions will normally be required.	N/A – There are no separate Tier 2 SSTLs for this pathway. If the Tier 1 RBSLs are exceeded, remedial actions will normally be required.	

NOTE: Use of a direct push technology for the installation of permanent ground water monitoring wells is currently not an acceptable method under Title 178. If direct push techniques are used for Tier 2 sample collection, the Department may require subsequent installation of permanent monitoring wells if the site requires remediation or additional monitoring.

Tier 2 investigations may require sampling locations on lands adjoining the source area property. To avoid unnecessary delays, prospective off-site locations should be identified and access permission obtained as early in the Tier 2 process as possible. If a property owner refuses to grant permission for access and no suitable alternative location is available, the PRS Project Manager should be contacted for assistance. The property owner's name, phone number, and the location of the property in question should be provided.

6.1 – MINIMUM TIER 2 SITE ASSESSMENT DATA REQUIREMENTS

The minimum investigation requirements needed for a Tier 2 site assessment are presented below for each of the exposure pathways. The Tier 2 investigation is to collect only that information necessary to evaluate specific pathways that failed the Tier 1 evaluation.

6.1.1 – Ground Water Ingestion Pathway

1. Monitoring points must be installed to collect ground water samples for laboratory analysis of the COCs and relevant site-specific aquifer parameters. Monitoring points are to be placed in such a manner that the dissolved plume is areally delineated in all directions from the source area(s) to the specific COC levels found in Table 4-2.
2. All monitoring points, including those monitoring wells from the previous Tier 1 investigation, are to be sampled for the necessary COCs.
3. Where a water supply well (as determined during the Tier 1 investigation) may be of sufficient proximity and/or pumping capacity to influence the dissolved product plume, or potential on-site or downgradient recharge areas exist, it must be determined if vertical migration of the dissolved plume is occurring. The methods or means (e.g., multiple monitoring wells screened at different intervals) used to collect this information are to be included in the Tier 2 workplan. Boring logs and pump screen interval depth(s) for the water supply well are to be submitted if available. If pumping data or other well use information is available for the water supply well, it is also to be included in the investigation report.
4. Depth to ground water is to be measured (after water levels have adequately stabilized) in all monitoring wells, including those installed during the Tier 1 as well as those installed as part of the Tier 2 investigation, for the purposes of determining the water table gradient and refining the ground water flow direction established during Tier 1.

6.1.2 – Soil Leaching to Ground Water Pathway

1. The extent of source area subsurface soil contamination (i.e., "soil contaminant plume") in the vadose zone is to be closely delineated using soil samples collected from borings or direct push soil sampling technologies. Sampling points are to be concentrated around the source area(s) identified during the Tier 1 assessment. Where possible, sampling points are to be placed outward from the source area (at approximately 90-degree angles to each other; see Figure 6-1) at 10- to 15-foot intervals until no field evidence of source area soil contamination is found. Where such sampling is not possible, the Department is to be consulted for alternate sampling requirements. Sampling points are to be continuously sampled to determine the location(s) of maximum soil contamination and to accurately describe the site geology. Sampling of soils should be avoided in locations away from the source area where field evidence indicates contamination may only be associated with the capillary fringe.
2. All borings are to be sampled for the COCs and submitted for laboratory analysis. The number of samples to be collected is specified in Section 6.1.2a, below.
3. Soil samples are to be collected for determination of the following physical/chemical parameters: dry bulk density, and fractional organic carbon content (see Section 6.2). The number of samples to be collected is specified in Section 6.1.2b, below.

Figure 6-1. Idealized Placement of Tier 2 Soil Sampling Points

6.1.2a Number of Soil Samples for COC Analysis

Where ground water is less than 25 feet BGL, one sample per boring is to be collected at the identified point of maximum contamination. Where ground water is greater than 25 feet BGL, two samples are to be collected: one sample within the first 25-foot interval and the second from between 25 feet BGL and the water table. Both samples are to be obtained from points of maximum evident contamination.

NOTE: The number of COC soil samples required from each boring for Tier 2 is different than for Tier 1. Be sure to refer to the correct section when planning or conducting investigations.

6.1.2b Number of Soil Samples for Chemical and Physical Parameter Analysis

One sample is to be collected for each parameter specified in Section 6.2.3 from each sediment type present at the site.

6.1.3 – Intrusion of Vapors to Structure from Contaminated Ground Water Pathway

This pathway concerns the migration of vapors from contaminated ground water into structures. It may be assessed in either of two possible ways: using ground water samples or using soil vapor samples. Both are equally acceptable.

Regardless of which option is chosen, all subsurface structures must be assessed for the presence of vapors as specified in Section 4.7.4. If vapors are detected in any buildings or other subsurface structures, the notification guidance outlined in Table 2-1 should be followed. The results of the vapor assessment must be submitted in the Tier 2 report.

6.1.3.1 Ground Water Sampling Option

1. Collect ground water samples for laboratory analysis of the COCs. Monitoring points are to be located to delineate the dissolved plume COCs to the levels found in Table 4-2.
2. Soil samples must be collected above the estimated capillary zone for determination of the volumetric water content, dry bulk density, and fractional organic carbon content (see Section 6.2).
3. Depth to ground water is to be measured in all monitoring wells (after water levels have adequately stabilized) for the purposes of determining the water table gradient and refining the ground water flow direction established during Tier 1.
4. All monitoring points are to be sampled for the COCs and the samples submitted for the appropriate laboratory analysis.
5. A survey of structures within the contaminant plume must be performed, and a list of building owners (or owners' representatives), daytime telephone numbers, mailing addresses, and typical uses of space (e.g., residence, daycare, storage, etc.) must be provided in the Tier 2 Investigation Report. It is important to determine if the buildings have basements or similar structures.

6.1.3.2 Soil Gas Sampling Option

1. Monitoring points must be installed above the estimated capillary zone, in the following locations:
 - The source area(s), within three feet of the water table or saturated zone;
 - Adjacent to all on-site and the nearest off-site habitable structures, at a depth slightly less than the bottom of the building's footings, or three feet BGL, whichever is greater; and,
 - At least one location between the source area(s) and each structure, within three feet of the estimated capillary zone.
2. Soil gas samples must be collected from each monitoring point in accordance with Section 6.3.1.
3. A survey of structures within the contaminant plume must be performed, and a list of building owners (or owners' representatives), daytime telephone numbers, mailing addresses, and typical uses of space (e.g., residence, daycare, storage, etc.) must be provided in the Tier 2 Investigation Report. It is important to determine if the buildings have basements or similar subgrade structures.

6.1.4 – Intrusion of Vapors to Structure from Contaminated Subsurface Soils Pathway

This pathway concerns the migration of vapors from contaminated subsurface soils into structures. It may be assessed in either of two possible ways: using soil samples or using soil gas samples. Both are equally acceptable.

Regardless of which option is chosen, all subsurface structures must be assessed for the presence of vapors as specified in Section 4.7.4. If vapors are detected in any buildings or other subsurface structures, the notification guidance outlined in Table 2-1 should be followed. The results of the vapor assessment must be submitted in the Tier 2 report.

6.1.4.1 Soil Sampling Option

1. The extent of source area subsurface soil contamination (i.e., "soil contaminant plume") within the upper 25 feet of the vadose zone around the release area is to be closely delineated using soil borings. Borings are to be concentrated in the source area(s) identified in the Tier 1 assessment. Where possible, borings are to be placed around each source area (at approximately 90-degree angles to each other; see Figure 6-1) at 10- to 15-foot intervals outward until no field evidence of soil contamination is found. If habitable buildings are present over or near the soil contaminant plume, at least one boring is to be located as close as possible to each building, between the building and the source. Where such sampling is not possible, the Department is to be consulted for alternate sampling requirements. Borings are to be continuously sampled to determine the assumed or perceived location(s) of maximum soil contamination and to accurately describe the site geology.
2. Samples for the COCs are to be collected from all borings and submitted for laboratory analysis. The number of samples to be collected is specified in Section 6.1.4.1a, below.

3. Soil samples are also to be collected for determination of the following parameters: dry bulk density, fractional organic carbon content, and volumetric water content (see Section 6.2.). The number of samples to be collected is specified in Section 6.1.4.1b, below.
4. A survey of structures located over the soil contaminant plume must be performed, and a list of building owners (or owners' representatives), daytime telephone numbers, mailing addresses, and typical uses of space (e.g., residence, daycare, storage, etc.) must be provided in the Tier 2 Investigation Report. It is important to determine if the buildings have basements or similar subgrade structures.

6.1.4.1a Number of Soil Samples for COC Analysis

Two subsurface soil samples are to be analyzed from each sampling point. These samples are to be collected at the points where the highest level of contamination is measured by field instrumentation and are to be obtained within the initial 25 feet BGL or at points above the ground water table, whichever is less.

NOTE: The requirements for this pathway are different than for the Soil Leaching to Ground Water pathway (Section 6.1.2a). Make sure that the samples collected satisfy the requirements of all applicable exposure pathways.

6.1.4.1b Number of Soil Samples for Chemical and Physical Parameter Analysis

One sample is to be collected for each parameter specified in Section 6.2.3 from each sediment type present at the site.

6.1.4.2 Soil Gas Sampling Option

1. Monitoring points must be installed above the estimated capillary zone, in the following locations:
 - The source area(s), within the soil contaminant mass;
 - Adjacent to all on-site and the nearest off-site habitable structures, at a depth slightly less than the bottom of the building's footings, or three feet BGL, whichever is greater; and,
 - At least one location between the source area(s) and each structure, within the soil contaminant mass.
2. Soil gas samples must be collected from each monitoring point in accordance with Section 6.3.1.
3. A survey of structures within the contaminant plume must be performed, and a list of building owners (or owners' representatives), daytime telephone numbers, mailing addresses, and typical uses of space (e.g., residence, daycare, storage, etc.) must be provided in the Tier 2 Investigation Report. It is important to determine if the buildings have basements or similar subgrade structures.

6.2 – VADOSE ZONE SOIL CHARACTERISTICS

Certain soil parameters or characteristics used in the Department's fate and transport equations are to be selected based on the predominant soil type or determined by sampling and laboratory analysis during the Tier 2 assessment. This section provides and discusses the parameters for which the Department requires site-specific information used in the calculation of the Tier 2 SSTLs.

NOTE: The boring location, depth, and sediment type from which each of the samples is collected for Sections 6.2.2 and 6.2.3 must be documented in the Tier 2 report.

6.2.1 – Soil Porosity

Porosity is a variable used in the Tier 2 fate and transport equations for all exposure pathways examined by the Department. Estimated values for soil porosity are to be selected from Table 6-2.

Table 6-2. Estimated Soil Porosity Values

Sediment Type	Porosity
Clay	0.42
Silt/Loess	0.47
Till, predominantly silt	0.34
Till, predominantly sand	0.31
Sand, fine	0.43
Sand, medium	0.39
Sand, coarse	0.39
Gravel, fine	0.34
Gravel, medium	0.32
Gravel, coarse	0.28

Source: Adapted from Todd (1980)

6.2.2 – Capillary Zone Thickness

The relatively greater percentage of pore water in the capillary zone, compared to that of the overlying vadose zone, has a limiting effect on the diffusion of contaminant vapors partitioning from a contaminant plume dissolved in ground water. When examining the intrusion of vapors to a structure for the contaminated ground water exposure pathway, information regarding the capillary zone thickness and its volumetric water content (see Section 6.2.3.2) must be obtained. Conservative estimated values for capillary zone thickness, based on predominant sediment type, are to be selected from Table 6-3.

Table 6-3. Estimated Capillary Zone Thickness

Sediment Type	Capillary Zone Thickness (cm)
Silt/Clay	105
Sand (fine)	42
Sand (medium to coarse)	13.5
v. coarse Sand to fine Gravel	2.5
Gravel (medium to coarse)	0

Source: Adapted from Todd (1980)

6.2.3 – Chemical and Physical Parameters

Site-specific values for soil dry bulk density, volumetric water content, and fractional organic carbon content in soil are required to calculate SSTLs for the following indirect exposure pathways:

- Soil leaching to ground water
- Intrusion of vapors to structure from contaminated ground water, except in cases where only the inhalation pathway is applicable and soil gas samples are collected instead of ground water
- Intrusion of vapors to structure from contaminated subsurface soils, except in cases where only the inhalation pathway is applicable and soil gas samples are collected instead of subsurface soils

All samples for these parameters must be collected in the vadose zone. Specific requirements are provided below.

6.2.3.1 Dry Bulk Density

6.2.3.1a Number of Samples

The number of samples needed for the analysis of dry bulk density depends on the stratigraphy of the vadose zone. One representative sample is required for each sediment type encountered.

6.2.3.1b Sample Collection Methods

Samples obtained for dry bulk density analysis are to be collected using a thin-walled tube sampler for clay samples in general accordance with ASTM D-1587, a split-barrel sampler for sand samples in general accordance with ASTM D-4220, or some other method approved by the Department.

6.2.3.2 Volumetric Water Content

6.2.3.2a Number of Samples

One representative sample is required for each sediment type encountered within the vadose and capillary zones.

6.2.3.2b Sample Collection Methods

Samples obtained for volumetric water content analysis are to be collected using a thin-walled tube sampler for clay samples in general accordance with ASTM D-1587, a split-barrel sampler for sand samples in general accordance with ASTM D-4220, or some other method approved by the Department. Samples obtained for volumetric water content analysis are to be placed in a small glass jar and tested as described in ASTM Standard D-2216 or some similar method approved by the Department. Results are to represent a volumetric value. Laboratory results provided for gravimetric values are to be converted to and reported as volumetric values using the following relationship:

$$\theta_{\text{vv}} = \theta_{\text{wg}} \times \frac{\rho_{\text{s}}}{\rho_{\text{w}}}$$

where: θ_{vv} = volumetric water content (cm³-water/cm³-soil)
 θ_{wg} = gravimetric water content (grams-water/grams-dry soil)
 ρ_{s} = dry bulk soil density (grams-dry soil/cm³-soil)
 ρ_{w} = density of water (grams-water/cm³-water) = 1

6.2.3.3 Fractional Organic Carbon Content in Soil

6.2.3.3a Number of Samples

The number of samples needed for the analysis of fractional organic carbon content is dependent on the sediment types present in the vadose zone. One representative sample is required for each sediment type within which contamination has been encountered; however, the sample(s) must be obtained from uncontaminated soils to avoid analysis interference from organic carbon associated with the petroleum contamination.

6.2.3.3b Sample Collection Methods

Samples obtained for fractional organic carbon content analysis are to be collected in a small glass jar and tested as described in ASTM Standard D-2974 or some similar method approved by the Department.

6.3 – DISTRIBUTION OF COCS IN SOIL VAPOR

At the Tier 2 level, soil gas sampling may be substituted for other media sampling (with the approval of the Department) for the following exposure pathways once the ground water flow direction has been established:

- Intrusion of vapors to structure from contaminated ground water (see Section 6.1.3.2).
- Intrusion of vapors to structure from contaminated subsurface soils (see Section 6.1.4.2).

The requirements for the number and location of sample points are presented in the referenced Sections.

6.3.1 – Soil Gas Sampling Point Installation

Soil gas sampling points may be temporary or permanent. Permanent monitoring points should be constructed with similar diameters, materials, surface seals, and screen lengths. Acceptable installation methods include:

- Direct push
- Auger drilling
- Hand-installed (generally limited to through-floor points inside buildings or other structures; specify in the workplan or contact the PRS Project Manager for approval)

6.3.2 – Soil Gas Sample Collection Methods

Soil gas samples are to be collected using the following criteria:

1. The sampling point is sufficiently sealed to prevent the introduction of ambient air into the sample;
2. The sample point is purged prior to sampling to ensure a representative sample of soil gas is collected (purging times and volumes to be included in investigation narrative);
3. The soil gas sample is to be collected and analyzed using one of the following protocols:
 - In the field using a lab-quality gas chromatograph to avoid loss of volatiles in transport;
 - in a summa canister or similar collection device and submitted for laboratory analysis; or
 - in a Tedlar® bag or similar collection device and submitted for laboratory analysis, provided that such analysis takes place within three days (72 hours) of sample collection. If the three-day limit is exceeded, costs for obtaining a replacement sample and performing a second analysis will not be eligible for reimbursement under Title 200.

The QA/QC documentation described in Section 4.9.5 is required, but no duplicate samples or field and trip blanks are necessary for soil gas samples. If using an analytical laboratory, follow their recommendations for transport of the samples. If using in-field analytical equipment, the analysis reports, company name, and analyst's name must be submitted with the Tier 2 investigation report.

6.4 – TIER 2 REPORTING REQUIREMENTS

The Department has established a reporting format that the RP or their consultant must use to submit the investigation results. The report format consists of Report Forms generated in Microsoft Excel for most of the required data. The Tier 2 Report Forms have been revised to incorporate the changes in this guidance document, and are located in the Department's RBCA software package under the Excel file: *TIER_2_FORMS.xls*. The forms are illustrated in Appendix C. Copies of these forms in Microsoft Excel format may be downloaded from the Department's website (www.deq.state.ne.us).

If any alternate methods from the procedures presented in this document were used in the investigation, they must be prominently noted in the report and an explanation provided. Cross sections, sampling data, and any other information in addition to that included in the Report Forms are to be provided in the general formats discussed under Section 4.10.

SECTION 7.0 – RISK-BASED EVALUATION: GENERAL CONSIDERATIONS

7.1 – INTRODUCTION

The Tier 1 and Tier 2 RBCA evaluations are performed by the Department using the assessment information collected by the responsible parties and their consultants. Sections 7.0, 8.0 and 9.0 of this document outline the procedures and parameters the Department uses for the evaluations.

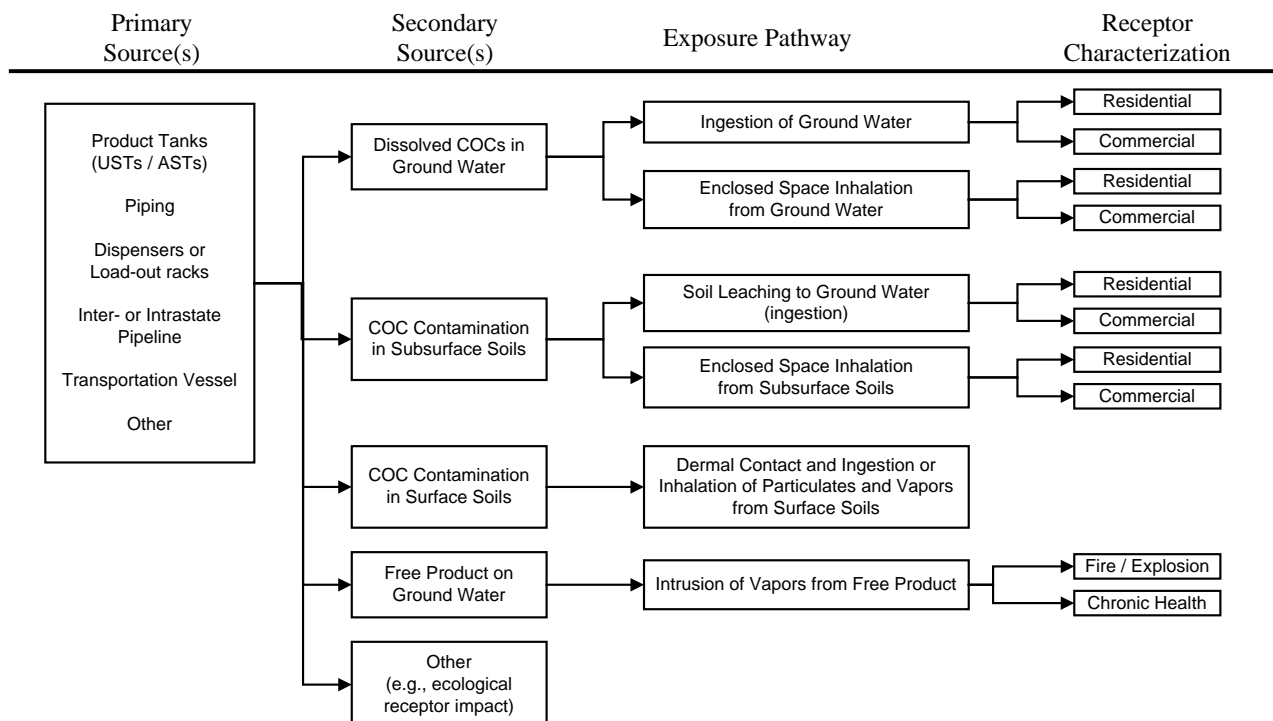

NOTE: While the Department may provide additional material (e.g., computational computer software) to interested parties, an RP and their consultant will only be responsible for providing the site data and information outlined in previous sections of the document and the Report Forms provided by the Department. Any evaluation of the site, other than that required by the Department, will not be eligible for Title 200 reimbursement consideration for those sites that are eligible for reimbursement.

After the appropriate site assessment data has been collected, it is used to evaluate the release based on risk considerations. The initial action is to develop a site-specific exposure scenario wherein several general factors (i.e., current and potential land use, receptors, points of exposure and potential routes of exposure) are examined to determine where any potential exposures are most likely to occur. Subsequently, target levels are determined for all complete exposure scenarios. At the Tier 1 level, this consists of comparing the COC levels encountered during the site assessment to initial RBSLs developed from non-site-specific criteria. At the Tier 2 level, this consists of comparing the COC levels encountered during the site assessment to SSTLs calculated using site-specific data. The need for initial abatement actions, monitoring and/or long-term active cleanup is determined by the Department.

7.2 – DEVELOPMENT OF SITE CONCEPTUAL EXPOSURE SCENARIO

A Site Conceptual Exposure Scenario for each release is developed using the information gathered during the investigation process to characterize the exposure pathways at risk due to the release. General factors to be examined during the development of the Site Conceptual Exposure Scenario include current and potential land use, receptors, points of exposure, and potential routes of exposure. The exposure scenario is displayed in graphical form in Figure 7-1.

Figure 7-1. Site conceptual exposure scenario

7.2.1 – Land Use

As discussed in Section 4.4, the Department classifies each site as “Residential” or “Commercial” based on land use within a 500-foot radius of the site. “Residential” refers to the presence of dwellings (e.g., houses, apartments) and/or sensitive population centers (e.g., schools, day care centers, hospitals, nursing homes). Sites that cannot be classified as residential are characterized as being in a “Commercial” setting. In addition, potential changes in future land use must be investigated.

7.2.2 – Receptors & Points of Exposure

“**Receptor**” refers to any humans potentially exposed to petroleum COCs.

“**Points of Exposure**” (POE) refers to the locations at which the receptor is potentially exposed, such as water wells or basements. Points of exposure may be actual or hypothetical (future-use) locations, depending on ground water use or the location of structures in the area.

“**Ecological Exposure**” refers to locations where the COCs or free product from a petroleum release contact a lake, stream, wetland, or other surface water body with the potential to affect wildlife.

7.2.3 – Exposure Pathways of Concern

The Department examines petroleum releases to determine if the following exposure pathways are complete or incomplete:

- Dermal contact with, ingestion of, and outdoor inhalation of COCs emanating from contaminated surface soils;
- Enclosed space inhalation of COCs emanating from contaminated subsurface soils;
- Leaching of COCs from contaminated surface and subsurface soils to ground water;
- Enclosed space inhalation of COCs emanating from contaminated, shallow ground water; and,
- Ingestion of COCs from contaminated ground water.

Surface soils are defined as those unsaturated materials located between 0 and 3 feet BGL. Subsurface soils are defined as those unsaturated materials located ≥ 3 feet BGL. For the enclosed space inhalation exposure pathway from shallow ground water, “shallow” is defined as ground water less than 15 feet below the base of a structure or 15 feet BGL where no structure is present. Idealized exposure pathways are illustrated in Figures 7-2 and 7-3.

For an exposure pathway to be considered complete, the following conditions must be met:

1. A source and mechanism must be present for petroleum COCs to be released into the environment;
2. A transport medium must be present (e.g., ground water, soil vapor) for the COCs to travel from the source to the POE (e.g., drinking water well, basement);
3. A potential POE (including potential future use) in contact with the medium must be documented (e.g., a drinking water well); and,
4. An exposure route or means for taking COCs into a human body must be possible (e.g., ingestion of water, inhalation of vapors).

In cases where an exposure pathway is not complete under both current and future conditions, that particular exposure pathway is not subject to a quantitative evaluation. All complete pathways are quantitatively evaluated, but may be eliminated with use of appropriate engineering control(s) (e.g., abandoning an on-site water supply well), provided the appropriate control(s) are implemented and effective.

Figure 7-2. Idealized Illustration of Ground Water Ingestion and Soil Leaching to Ground Water Exposure Pathways

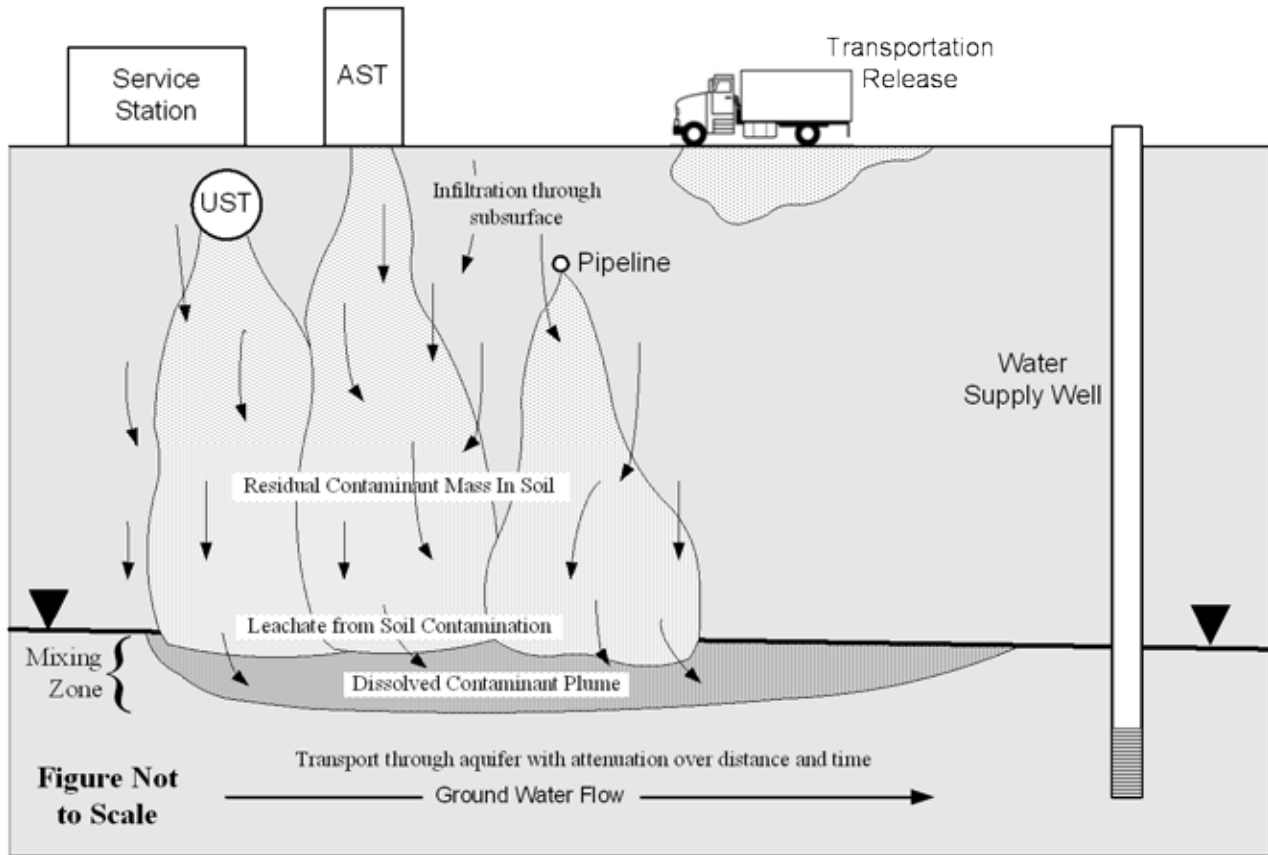

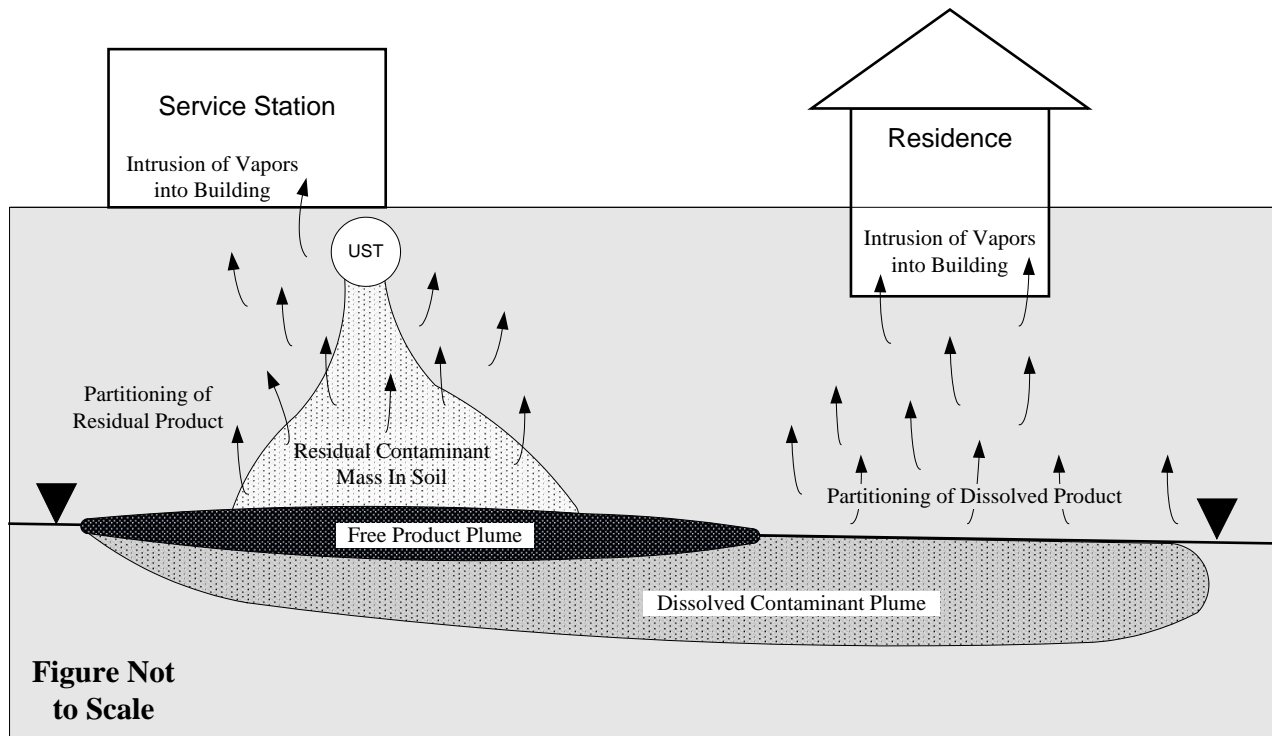

Figure 7-3. Idealized Illustration of Enclosed Space Inhalation Exposure Pathways

7.3 – CALCULATION OF TARGET LEVELS

“Target levels” refer to either the Tier 1 RBSLs or the Tier 2 SSTLs to which the contamination levels found during the site assessment are compared. Requirements for developing the target levels include:

- Allowable concentrations at a POE for ground water or surface water protection
- Target risk limits
- COC-specific physical and chemical properties
- COC-specific quantitative toxicity factors
- Human exposure factors
- Fate and transport parameters
- Mathematical models

7.3.1 – Allowable Concentration

The ground water ingestion and ecological exposure pathways have regulations in place (Title 118 for ground water, Title 117 for surface water) which prescribe the maximum contaminant levels (MCLs) allowable for certain COCs at points of exposure. These MCLs are the basis for the ground water ingestion, soil leaching to ground water, and ecological exposure scenarios.

7.3.2 – Target Risk Limit

The target risk limit is the starting point for development of the RBSLs and SSTLs. It represents the maximum level of individual risk that will be permitted by the Department when calculating an allowable or acceptable chronic intake of a COC into the human body.

The Department’s approach varies the target risk limits depending on the nature of the potential exposure. For RAC-1 sites that involve the potential ingestion of contaminated ground water, or for sites where inhalation of vapors or ingestion of contaminated soil is a present and ongoing concern, the most stringent target risk limits should be used. For sites that involve contamination of ground water categorized as RAC-2 or have the potential for inhalation concerns with no current building or structure present, slightly lower target risk limits are used. This difference allows the Department to appropriately address cases of varying exposure likelihood and consequence.

For definitions and a more detailed explanation of Remedial Action Classes, see Section 7.4.1.

7.3.2.1 Carcinogenic Effects

MCLs, or an equivalent concentration selected by the Department when an MCL has not been promulgated for a particular COC, are used to calculate the appropriate target levels for carcinogens for pathways involving the chronic ingestion of ground water classified as RAC-1. Values for Individual Excess Lifetime Cancer Risk (IELCR) are used for all other situations involving carcinogenic effects. Table 7-1 summarizes the applicable target risk limits for the various pathway/RAC combinations.

Table 7-1. Target Risk Limits for Carcinogenic Effects

Exposure Pathway	Target Risk Limit
Ground Water Ingestion (RAC-1)	MCL
Soil Leaching to Ground Water (RAC-1)	MCL
Inhalation from soil or ground water (structure present)	IELCR = 10^{-6}
Dermal contact/soil ingestion	IELCR = 10^{-6}
Ground Water Ingestion (RAC-2)	IELCR = 10^{-5}
Soil Leaching to Ground Water (RAC-2)	IELCR = 10^{-5}
Inhalation from soil or ground water (no structure present)	IELCR = 10^{-5}

7.3.2.2 Non-carcinogenic Effects

MCLs, or an equivalent concentration selected by the Department when an MCL has not been promulgated for a particular COC, are used to calculate the appropriate target levels for non-carcinogens for both pathways involving the chronic ingestion of ground water classified as RAC-1. Hazard Indices (HI) are used for all other situations involving non-carcinogenic COCs. Table 7-2 summarizes the applicable target risk limits for the various pathway/RAC combinations.

Table 7-2. Target Risk Limits for Non-Carcinogenic Effects

Exposure Pathway	Target Risk Limit
Ground Water Ingestion (RAC-1)	MCL
Soil Leaching to Ground Water (RAC-1)	MCL
Inhalation (structure present)	HI = 1
Dermal contact/soil ingestion	HI = 1
Ground Water Ingestion (RAC-2)	HI = 10
Soil Leaching to Ground Water (RAC-2)	HI = 10
Inhalation (no structure present)	HI = 10

7.3.2.3 Additive effects

Carcinogens. Additivity of cancer risk is not explicitly considered at either the Tier 1 or Tier 2 level for several reasons. First, the listed DEQ carcinogenic COCs (benzene, ethylbenzene, naphthalene, and benzo(a)pyrene (BaP)) each affect different parts of the body. Second, it is assumed that the number of exposure pathways that may be considered complete is limited at any particular site. Third, the conservative assumptions used in the generation of the target levels are assumed to provide a margin of safety in this regard. Lastly, target levels calculated using an MCL (as for the ground water ingestion pathway) are not readily comparable to target levels when calculated using a specific IELCR (as for the enclosed space inhalation pathways).

Non-carcinogens. The HI represents the sum of all Hazard Quotients (HQs) for each COC affecting the same target organs and causing the same adverse health effect. For the purposes of the Tier 1 and Tier 2 assessments, benzene, toluene, ethylbenzene and total xylenes are considered to have additive health effects. While the carcinogenic effects of benzene and ethylbenzene outweigh their non-carcinogenic effects (meaning the target levels for these COCs are based on their carcinogenic effects), their additive effect in combination with toluene and total xylenes must be taken into account.

In Tier 1, a cumulative HI = 1 (or =10 for RAC-2 releases or where no structure is present for inhalation concerns) for additive effects of the BTEX compounds is established by assigning an HQ = 0.25 (or =2.5) to each individual compound. In Tier 2, additivity is addressed by totaling the cumulative risk for each individual BTEX component using the ratio between the actual site concentrations and the appropriate SSTLs for each exposure pathway. That is, SSTLs for each BTEX component are calculated using an HQ = 1, and the ratio between the representative concentration and the calculated SSTL is determined. If the sum of the BTEX ratios is ≤ 1 , the BTEX contamination is considered to pose no risk from exposure.

7.3.3 – COC Physical & Chemical Parameters

Appendix D, Table D-1 provides the pertinent physical and chemical properties used to establish or calculate the appropriate target level for each COC.

7.3.4 – COC Quantitative Toxicity Factors

Appendix D, Table D-2 provides the quantitative toxicity factors used to establish or calculate the appropriate target level for each COC.

7.3.5 – Human Exposure Factors

The applicable exposure factors (e.g., body weight, exposure duration) and the values used to calculate the appropriate target level for a residential and commercial receptor are provided in Appendix D, Table D-3.

7.3.6 – Fate & Transport Parameters

Appendix D, Table D-4 provides the pertinent data parameters and default values used in the fate and transport models and to determine the appropriate target level for each COC. General comments concerning these parameters include:

- Unless otherwise noted in this section, default values are taken directly from the ASTM E-1739 Standard Appendix.
- Values for the calculation of source area (30 feet by 30 feet) are based on a review of tank removal reports and are reflective of a typical service station where 3-4 tanks are located in a single excavation.
- Default values for the saturated hydraulic conductivity, hydraulic gradient, total porosity of the saturated zone, infiltration rate, and fractional organic carbon content vary between Tier 1 lookup tables.
- Thickness of the mixing zone (default: 5 feet) is based on the general monitoring well construction practice for petroleum releases of screening a well with the ground water/unsaturated zone interface at the mid-point of the well screen length (commonly 10 feet).
- The unsaturated zone concentration reduction factor (CRF) varies with depth to ground water. The possible values of 1 and 2 are empirical depending on the depth to ground water.

7.3.7 – Mathematical Models

Mathematical equations are used to model the fate and transport of contaminants in the environment and the human uptake of contaminants as a result of chronic exposure. Fate and transport models calculate the reduction in COC concentrations as COCs move from the source to the POE; data inputs include various soil and aquifer parameters and the physical and chemical properties of the COCs. Uptake models estimate the quantities of COCs ingested, inhaled, or

absorbed by humans as a result of chronic contact with COCs at the POE; data inputs include the physical and chemical properties of the COCs and representative physiological values for adults and children.

The equations used in the calculation of the Tier 1 RBSLs and Tier 2 SSTLs are summarized in Appendix E. Default values for input into these equations are discussed in Section 7.3.6 and provided in Appendix D. Chemical-specific data are also provided in Appendix D. The models used are:

- Domenico and Summers models for back-calculating allowable dissolved COC concentrations in ground water from a POE and allowable soil leachate concentrations from those ground water concentrations.
- Farmer's model for calculating soil and ground water concentrations protective of indoor inhalation.
- USEPA's model (1991) for estimating outdoor inhalation from surface soils.
- USEPA's models (1991) for estimating uptake.

7.4 – PROTECTION OF GROUND WATER

The following is provided from Nebraska Title 118 – *Ground Water Quality Standards and Use Classification*, Appendix B – Remedial Action Protocol for Petroleum Releases, Step 7:

“Most ground water in the principal aquifer (closest underlying major aquifer) is of drinkable quality and is used by nearly all Nebraskans as drinking water. Water of drinking water quality is usually suitable for all other beneficial uses. For these reasons, protecting ground water for drinking water use is most important and normally protects it for all uses.”

In addition to the protection of ground water itself, consideration must also be given to residual contamination in soils as a source of continued ground water contamination. Considerations to be made for the protection of ground water are provided below.

7.4.1 – Remedial Action Classes (RACs)

Protection of ground water as a drinking water source under Title 118 directly relates to the Remedial Action Class (RAC) established for the release by the Department. The RAC categories are not intended to represent a ground water classification system, but rather a pollution release-ranking scheme. It gives the Department a method to determine the importance of remedial action based on the use of the ground water. RACs are determined by:

- The location of drinking water wells in the area of the release;
- Potential future drinking water use considerations; and,
- The degree of ground water contamination encountered during the Tier 1 and Tier 2 investigations

A RAC is defined for pollution occurrences in three types of ground water (or overlying soils) depending on the degree (or potential) of use of the ground water as drinking water. The extent of remedial action required will differ depending, in part, on the RAC of the contaminated (or likely to be contaminated) ground water. (Note that the RAC assigned is determined from the condition of the ground water prior to the occurrence of pollution. The Department will do this based on information submitted by the RP in the RBCA Tier 1 and Tier 2 site investigations and other available information.) Below are definitions of the three RAC categories followed by some further explanation. (Definitions of Classes GA, GB, GC and GC(R) can be found in Title 118, Chapter 7 and Appendix B. Class GA waters also include designated Wellhead Protection Areas [WHPAs].)

RAC-1. This category includes ground waters of Class GA (ground water used or proposed to be used for a public drinking water source) and a portion of Class GB (ground water currently being used as a private drinking water source), and ground water within a designated WHPA. In addition, RAC-1 shall be automatically assigned anytime a public or private drinking water supply well has been polluted. RAC-1 will usually receive the most extensive remedial action measures.

RAC-2. This category includes ground waters of Class GB (except for the portion of Class GB placed in RAC-1; i.e., ground water with the potential to be used as public or private drinking water source) and Class GC(R) (ground water resources where the Department determines that restoration or cleanup may be appropriate).

RAC-3. This category includes, but is not limited to, ground waters of Class GC (except for Class GC(R) which was placed in RAC-2; i.e., ground water not currently used and has little or no potential to be used as a public or private drinking water source). RAC-3 will usually receive the least extensive remedial action measures.

RAC-1 is the category of highest rank; it represents that ground water actually being used for drinking water and that ground water intended to be used in a public drinking water supply. Therefore, RAC-1 occurrences will normally receive the most conservative RBCA target levels and most extensive remedial action measures.

RAC-2 occurrences involve ground water currently not used as drinking water, but having a reasonable potential to be used in the future. Potential use exists if the ground water is located in a highly populated area or is part of a regional, high-yielding aquifer, or if otherwise justified. The RAC-2 category also includes ground water with prior contamination that may be treated easily or cost-effectively to drinking water quality.

RAC-3 pollution occurrences are of lowest importance if the ground water involved is not used, or not likely to be used, as drinking water. Generally, remedial action measures will be least extensive for this category since the future use of such ground water as a drinking water supply is improbable. Justification for assigning occurrences to RAC-3 is based on a combination of factors, including:

- The water is of such poor natural quality that it is unfit for human consumption.
- Insufficient yield may limit or exclude the ground water being used for drinking water.
- Historical contamination may have contaminated the ground water to a point that it is not suitable for consumption [see NRS § 81-1505(2)(d)]. This historical contamination may now be uneconomical to treat.
- Past and present intensive land use may also be a reason why ground water could be unusable as drinking water. This includes areas of concentrated industrial development or densely populated areas where ground water is likely to be contaminated or will not be used as drinking water.

7.4.2 – Location and Type of Water Supply Wells

Water supply wells must be located and documented during the Tier 1 site investigation in accordance with Sections 4.3.2 and 4.4.3. Water supply wells include municipal, domestic, irrigation, industrial or any other well from which water is withdrawn for beneficial purposes. Water supply wells do not include monitoring wells or recovery wells used for corrective actions.

At the Tier 1 level, all water supply wells documented in accordance with Sections 4.3.2 and 4.4.3 are treated as potential POEs (see also, Section 7.4.4, Step 1). At the Tier 2 level, only those wells that may be impacted by the contaminant plume are considered potential POEs. This determination is based on the orientation and extent of the contaminant plume, along with consideration of the effects of any pumping wells on the contaminant plume.

In defining a RAC, Title 118 only refers to drinking water supply wells, or ground water used or capable of being used as drinking water. This emphasis on drinking water creates a potential dilemma in the RBCA process where RAC-2 designation is assigned to a site (and correspondingly higher target levels are used compared to a RAC-1 situation); consequently, a nearby non-drinking water well (e.g., irrigation well, industrial well) may not receive the appropriate protection. Therefore, in the RBCA evaluation process, drinking and non-drinking water wells will be examined separately. To remain protective of beneficial ground water use for a non-drinking water supply well, target levels are set at ten times the level for a drinking water supply well, given the same site characteristics.

7.4.3 – Location of Compliance Wells

A point of compliance (POC) is a location within a source area or between a source area and the potential POEs where the concentrations of COCs must be at or below the determined target levels. For Tier 1, the borings/monitoring wells located within the source area(s) are the compliance point(s) for subsurface soil and ground water. At Tier 2, additional compliance points are set at select locations between the source area(s) and a potential POE for which individual SSTLs are calculated. These wells are located to monitor and assess the dynamics of the contaminant plume. They will also help to assess the validity of the fate and transport equations used by the Department and to ensure that ground water concentrations are decreasing (see also Section 7.4.4, Step 3).

7.4.4 – Calculation of Target Levels Protective of Ground Water

Target levels for soils and water that are protective of ground water and water supply wells (i.e., POEs) in the area are determined as provided below. The key steps in these calculations include:

1. Identification of POEs;
2. Target concentrations at a POE;
3. Identification of appropriate POCs (see Section 7.4.3);
4. Target concentrations at a POC; and,
5. Target concentrations in the source soils.

7.4.4.1 Identification of POEs

The identification of POEs is based on: 1) the RAC of the release and 2) the existence and type of water supply wells (drinking vs. non-drinking wells) near the site. For RAC-1 releases, the POE of most concern is the closest of the following:

- Municipal wells within 1000 feet,
- Domestic, irrigation and industrial wells within 500 feet,
- Sand points and hand-pump wells within 500 feet, and
- A hypothetical POE at a distance of 750 feet where the RAC-1 designation is based on the presence of a Wellhead Protection Area (WHPA).

Where a non-drinking water well (e.g., irrigation or industrial well) in a RAC-1 area is closer to a source area than a drinking water well, an evaluation must be made of both the non-drinking water well and the nearest drinking water well. The more conservative target level will be established as the allowable COC concentrations.

For RAC-2 releases, a hypothetical drinking water well located at 500 feet from the source area is considered to be a POE.

For the Tier 2 evaluation, only those water supply wells that are downgradient, or other wells of sufficient proximity and/or pumping capacity to influence the migration of the contaminant plume, are considered potential POEs.

7.4.4.2 Target Concentrations at a POE

Allowable COC target concentrations at a POE in the Tier 1 and Tier 2 evaluations vary based on the RAC designation of the release. The levels for RAC-1 releases in both tiers are based on MCLs (or other levels) for the individual COC. Where a non-drinking water well is in closer proximity to a source area than a drinking water well in a RAC-1 situation, allowable target levels at the well are calculated at ten times the RAC-1 allowable level.

The allowable target concentrations at a POE for a RAC-2 release in a Tier 1 evaluation are calculated assuming ingestion of water with the following target risk limits:

- Carcinogens: IELCR = 10^{-5}
- Non-carcinogens: HQ for BTEX = 2.5; for others = 10

For a RAC-2 release in a Tier 2 evaluation, the HQ for BTEX = 10, and is based on the sum of the ratios of the representative site concentrations to the allowable intake concentration of the individual BTEX constituents.

Table 7-3 provides the allowable COC concentrations at a POE for various ground water uses.

Table 7-3. Allowable COC Target Concentrations (mg/L) at a POE

Chemical of Concern	RAC-1	Non-Drinking Well	RAC-2
Benzene	0.005	0.050	0.015
Toluene	1.000	10.000	18.25
Ethylbenzene	0.700	7.000	9.13
Xylenes	10.000	100.000	182.50
n-Hexane	4.000	40.000	13.00
MTBE	0.020	0.200	0.47
Naphthalene	0.020	0.200	7.30
TEH (as diesel)	10.000	100.00	11.67
TEH (as waste oil)	6.660	66.600	38.80

In both RAC-1 and RAC-2 sites, soil and POC target concentrations must be protective of the identified POEs. For RAC-3 sites, the ground water ingestion pathway is considered incomplete; however, the inhalation exposure pathways and free product concerns must be considered.

7.4.4.3 Target Concentrations at a POC and Source Soils

The Department establishes target levels for POCs and source area soils by back-calculating allowable contaminant levels in ground water from a POE to the source area(s) and/or other compliance wells. In Tier 1, the target levels are RBSLs established using non-site specific criteria; at Tier 2, the Department calculates the SSTLs for each appropriate compliance well or location. The specific equations used to calculate compliance well target levels are provided in Appendix E.

7.4.5 – Protection of Deeper Ground Water

In areas where surface recharge and/or a water supply well(s) may be contributing to the vertical migration of a ground water contaminant plume, compliance wells screened at appropriate depths may be required by the Department to assess the vertical migration of the plume.

7.5 – PROTECTION OF INDOOR AIR QUALITY

To protect against the possibility of chronic health effects, indoor inhalation pathways are evaluated at every site during the Tier 1 investigation. If contaminant concentrations indicate, the pathways are examined in greater detail during the Tier 2. Target levels for ground water, soil, and soil gas are determined using the following steps:

1. Identification of POEs;
2. Target concentrations at a POE;
3. Target concentrations in soil gas, soils, and/or ground water.

Details of the calculation process are provided below.

7.5.1 – Identification of POEs

Any habitable structure situated above or adjacent to contaminated subsurface soils or ground water is considered a POE. In cases where more than one POE is present, an evaluation of each POE will be made. The most conservative target level will be used for the remainder of the calculations.

If no habitable structures are currently present and no evidence of suitable construction restrictions are presented, the Department will assume that such a structure could be built. The hypothetical structure will be considered the POE.

7.5.2 – Target Concentrations at a POE

Allowable COC concentrations at a POE in the Tier 1 and Tier 2 evaluations vary based on the characteristics of the POE. The primary distinctions are made between sites with existing structures and those that do not currently have a structure present. The allowable target concentrations are calculated using the following target risk limits for sites with existing structures:

- Carcinogens: IELCR = 1×10^{-6}
- Non-carcinogens: HQ for BTEX = 0.25, for others = 1.0

If no structure is present, the following target risk limits are used:

- Carcinogens: IELCR = 1×10^{-5}
- Non-carcinogens: HQ for BTEX = 2.5, for others = 10

A secondary consideration is the type of structure present or anticipated. Commercial structures are considered to be occupied by adults for limited periods of time, while Residential buildings are assumed to be continuously inhabited by both adults and children. The physical and chemical parameters listed in Appendix D are used in conjunction with the equations presented in Appendix E to determine the appropriate target concentrations.

For Tier 2 evaluations, the default values listed in Appendix D may be replaced with site-specific values determined during the investigation.

7.5.3 – Target Concentrations in Soil Gas, Soils, and/or Ground Water

The POE target concentrations are the allowable levels inside the structure. The target concentrations in soil gas, soil, or ground water are determined by back-calculating from the POE target concentrations using the parameters listed in Appendix D and the equations in Appendix E. Soil gas target levels are determined first, and the soil and ground water target concentrations are then calculated from those values. All calculations assume equilibrium conditions.

7.6 – PROTECTION FROM CONTAMINATED SURFACE SOILS

Potential exposures relating to contaminated surface soils involve dermal contact as well as the ingestion and inhalation of particulates. The physical and chemical parameters listed in Appendix D are used in conjunction with the equations presented in Appendix E to determine the RBSLs. The outdoor exposure to contaminated surface soils pathway is only evaluated at the Tier 1 level. If site concentrations exceed the Tier 1 RBSLs, surface soil cleanup will be required.

7.7 – PROTECTION OF SURFACE WATER, WETLANDS, AND ECOLOGY

Where surface waters or wetlands are threatened or have been impacted by a petroleum release, the Department will determine the appropriate mitigation measures to be taken on a case-by-case basis. Such measures may include free product recovery from the surface water, mitigating the continued discharge to the surface water body, or additional ecological assessment of the release. At a minimum, all pertinent Department surface water quality standards, as detailed in Nebraska Title 117 – Nebraska Surface Water Quality Standards, must be met for the impacted water body.

In instances where ecological exposures of threatened and endangered species habitat may be present or possible, the Department, in consultation with the Nebraska Game & Parks Commission, will determine the appropriate actions to be taken to mitigate the exposure. The extent of the assessment will be determined on a case-by-case basis.

7.8 – REPRESENTATIVE CONTAMINANT CONCENTRATIONS

In evaluating individual exposure pathways, the applicable RBSLs or SSTLs are compared to representative concentrations based on the analytical samples collected during the site investigation. To determine the representative site COC concentrations, the Department differentiates between *maximum* COC concentrations versus *average* COC concentrations.

7.8.1 – Representative Ground Water Concentrations

7.8.1.1. Ground Water Ingestion Pathway

For the ground water ingestion pathway, maximum COC concentrations are used. The fate and transport model used for this exposure pathway incorporates natural attenuation processes between two discrete points (i.e., between a water supply well and a source area). Because this model essentially deals with plume attenuation dominated in a single dimension (i.e., the direction of ground water flow), maximum COC concentrations are best used for the evaluation.

7.8.1.2. Enclosed Space Inhalation from Contaminated Ground Water Pathway

For evaluating the enclosed space inhalation pathways from contaminated ground water (and subsurface soils; see Section 7.8.2.2), the model used to calculate the appropriate RBSLs or SSTLs is based on the emission and diffusion of COCs over three dimensions. Because this model considers effects of area and depth for calculating contaminant emissions into a structure, it has been determined that averaging COC concentration levels is an appropriate means of establishing a representative contaminant concentration for these exposure pathways. The average contaminant concentration is calculated from samples with detectable levels of contamination taken immediately upgradient and surrounding the building. Samples that show non-detectable levels are not used to calculate the average concentration. Where no building is present, all ground water samples with detectable levels of contamination are used for calculating the average, assuming a building could be located on top of these locations.

7.8.2 – Representative Subsurface Soil Concentrations

7.8.2.1. Soil Leaching to Ground Water Pathway

Because petroleum, both in non-aqueous and dissolved phase, is leached from contaminated soils to ground water, which in turn greatly impacts the ground water ingestion pathway, the maximum subsurface soil COC concentration levels are used for evaluation.

7.8.2.2. Enclosed Space Inhalation from Contaminated Subsurface Soils Pathway

Like the inhalation from contaminated ground water exposure pathway, the Department uses the average of COC concentration levels to determine a representative contaminant concentration for this pathway. The average contaminant concentration is calculated from samples with detectable levels of contamination. Samples that show non-detectable levels are not used to calculate the average concentration.

Because soil samples may be obtained from variable depths within the vadose zone, an associated, average sample depth is needed as well. For the evaluation, the average depth of subsurface soil contamination is based on the following relationship (Salhotra, 2002, pers. com.):

$$d_{avg} = \frac{C_1 + C_2 + C_3 + \dots + C_n}{\left(\frac{C_1}{d_1} + \frac{C_2}{d_2} + \frac{C_3}{d_3} + \dots + \frac{C_n}{d_n} \right)}$$

where: d_{avg} is the average depth to the contaminant mass (in feet)
 C_n is the concentration of the n^{th} sample (in mg-contaminant/kg-soil), and
 d_n is the depth from which the n^{th} sample was obtained (in feet).

7.8.3 – Representative Surface Soil Concentrations

When multiple surface soil samples have been collected, the maximum concentration is considered representative of the COC concentration levels for the dermal contact with, ingestion of, and inhalation (through outdoor air) of COCs from contaminated surface soils.

7.8.4 – Representative Soil Gas Concentrations

The Department will use the average of soil gas concentrations from sampling points located in close proximity to existing structures as the representative concentration. If no existing structures are present, the average of all soil gas concentrations will be used. Samples with a concentration below the detection limit will not be used in calculating the average.

7.8.5 – Representative Indoor Air Concentrations

The Department will determine methods for determining appropriate representative concentrations for indoor air samples on a case-by-case basis.

SECTION 8.0 – TIER 1 EVALUATION

8.1 – STEP 1: DEVELOPMENT OF SITE CONCEPTUAL EXPOSURE SCENARIO

Using the information gathered from the Tier 1 site assessment pertaining to land use, ground water use, receptors and POEs, a site-specific Site Conceptual Exposure Scenario (see Figure 7-1) can be created to determine the complete exposure pathways.

To determine whether an exposure pathway may be considered complete or incomplete, the evaluation flowchart in Figure 7-1 is used to follow the release from its point(s) of leakage to the current or future point(s) of exposure. This provides a graphical representation of site conditions and potential exposure pathway impacts for evaluation. Provided below are pathway-specific criteria to be used to determine whether a pathway is complete.

8.1.1 – Ground Water Ingestion

The ground water ingestion exposure pathway is considered incomplete if any of the following conditions are met:

- Ground water has not been impacted and is not likely to be impacted.
- It has been demonstrated that contamination is limited to the overlying source areas, as detailed in Section 5.4.
- The release has received a RAC-3 designation, although free product must still be considered.

8.1.2 – Soil Leaching to Ground Water

The soil leaching to ground water exposure pathway is considered incomplete if subsurface soils (\leq 3' BGL) have not been impacted or the release has received a RAC-3 designation. Free product must still be considered.

8.1.3 – Intrusion of Vapors to Structure from Contaminated Ground Water

The intrusion of vapors to a structure from contaminated ground water exposure pathway is considered incomplete if any of the following conditions are met:

- Ground water has not been impacted.
- Ground water is demonstrated to be greater than 15 feet below floor level of a basement, crawl space or similar subsurface structure.
- Ground water is demonstrated to be greater than 15 feet below floor level of a building with no basement, crawl space or similar structure.
- Ground water is demonstrated to be greater than 15 feet below ground level where no building is present.

The depth to ground water is based on the shallowest depth encountered during the investigation, or the highest known ground water fluctuation.

8.1.4 – Intrusion of Vapors to Structure from Contaminated Subsurface Soils

The intrusion of vapors to a structure from contaminated subsurface soils exposure pathway is considered incomplete if any of the following conditions are met:

- Subsurface soils have not been impacted.
- The average depth of subsurface soil contamination is demonstrated to be greater than 15 feet below floor level of a basement, crawl space or similar subsurface structure.
- The average depth of subsurface soil contamination is demonstrated to be greater than 15 feet below floor level of a building with no basement, crawl space or similar structure.
- The average depth of subsurface soil contamination is demonstrated to be greater than 15 feet below ground level where no building is present.

8.2 – STEP 2: SELECTION OF RELEVANT TIER 1 RBSLS

For those exposure pathways that are complete or potentially complete, representative contaminant concentrations are compared to the Tier 1 RBSLs. To account for the considerable variability of sediment characteristics, aquifer properties and depth to ground water across Nebraska, the RBCA Tier 1 RBSLs have been developed for several different site conditions. The site conditions include the following:

- Land use scenarios (i.e., residential or commercial);
- Two default hydrogeological scenarios (see Table 8-1 below);
- RAC designation;
- Proximity of water supply wells;
- Thickness of the vadose zone; and,
- Presence/absence of on-site/off-site structures (e.g., buildings with or without basements)

The default hydrogeological scenarios are characterized by the factors provided in Table 8-1.

Table 8-1. Applicable Factors for Tier 1 Default Hydrogeological Scenarios

Factor	Hydrogeology 1 (Darcy Velocity < 0.1 ft/day)	Hydrogeology 2 (Darcy Velocity ≥ 0.1 ft/day)
Darcy velocity (cm/year)	111.25	11125
Porosity in vadose zone	0.35	0.30
Organic carbon content (g-C/g-soil)	0.01	0.005
Infiltration rate (cm/year)	3.8	7.6

The factors under the Hydrogeology 1 scenario are representative of a less permeable soil than that of Hydrogeology 2. Consequently, sites with predominantly silty and clayey soils would be assumed to fall under Hydrogeology 1 and sandy soils under Hydrogeology 2. Under Tier 1, the soils in the vadose zone and in the saturated zone are assumed to be homogeneous and have the same hydrogeological characteristics.

As part of the Tier 1 evaluation, the hydrogeological scenario to be utilized must be determined. The determination is based on the ground water Darcy velocity at the site. If the Darcy velocity is <0.1 feet/day (36.5 feet/year or 1112.5 cm/year), the site falls under Hydrogeology 1. The site falls under Hydrogeology 2 if the Darcy velocity is ≥ 0.1 feet/day.

The RBSLs calculated using these scenarios are provided in the Look-Up Tables in Section 8.3.

8.3 – STEP 3. COMPARISON OF RBSLS WITH REPRESENTATIVE CONCENTRATIONS

The appropriate RBSLs are selected from the Look-Up Tables for each complete or potentially complete exposure pathway and compared to the appropriate representative contaminant concentrations. The calculation of representative concentrations (maximum or average) for each pathway is discussed in Section 7.8.

The following Look-Up Tables are available:

GROUND WATER INGESTION

Representative concentrations are the maximum reported ground water concentrations for each COC.

- Table 8-2. Ground Water Flow Rate ≥ 0.1 feet/day
- Table 8-3. Ground Water Flow Rate < 0.1 feet/day

SOIL LEACHING TO GROUND WATER

Representative concentrations are the maximum reported soil concentrations for each COC.

- Table 8-4. Ground Water Flow Rate ≥ 0.1 feet/day
- Table 8-5. Ground Water Flow Rate < 0.1 feet/day

ENCLOSED SPACE INHALATION

Representative concentrations are average concentrations for each COC.

- Table 8-6. Residential Exposure; Building Present
- Table 8-7. Residential Exposure; No Building Present
- Table 8-8. Commercial Exposure; Building Present
- Table 8-9. Commercial Exposure; No Building Present

DERMAL CONTACT, INHALATION & INGESTION OF SURFACE SOILS

Representative concentrations are the maximum reported surface soil concentrations for each COC.

- Table 8-10. Allowable Contaminant Concentrations in Surficial Soils

SURFACE WATER OR ECOLOGICAL EXPOSURE

Representative concentrations are the maximum reported soil and/or ground water concentrations for each COC.

- Table 8-11. Surface Water Impact from Contaminated Ground Water
- Table 8-12. Surface Water Impact from Contaminated Soil Leaching to Ground Water

NOTES:

- 1) All RBSL concentrations in mg/L for ground water or mg/kg for soil.
- 2) RBSLs for volatilization hazards from all contaminants of concern are based on a structure within the source area.
- 3) These pathways are to be considered incomplete for releases of waste oil, as all determined RBSLs for this product are greater than the highest expected concentration in pure product.
- 4) > **Sol**: The target level is not exceeded for all possible dissolved levels.
- 5) > **Sat**: The target level is not exceeded for all possible saturated levels in soil.
- 6) RBSLs for benzene soil contamination in contact with an enclosed space may be below detection limits for most approved laboratory methods. This particular exposure pathway shall be considered clear if soil analytical results are non-detect at laboratory detection limits acceptable to the Department. The Department will provide guidance on acceptable detection limits at a later date.

NOTES:

- 1) All RBSL concentrations in mg/kg.
- 2) > Sat: The target level is not exceeded for all possible saturated levels in soil.

8.4 – STEP 4. SELECTION OF NEXT COURSE OF ACTION

The possible outcomes of the Tier 1 evaluation are as follows:

- Site closure;
- Removal/treatment of contaminated surface soils to meet Tier 1 levels (see DEQ Environmental Guidance Document 06-205: Management of Petroleum Contaminated Materials for disposal direction);
- Tier 2 investigation and assessment; and/or
- Implementation of remedial actions.

Details of actions that may be required are expressed below:

- If the concentrations for all COCs are less than the RBSLs for all applicable exposure pathways, then no additional actions will normally be required by the Department.
- Where the representative concentrations are at or above any of the RBSLs, other than those concerning the surficial soils pathways, an additional Tier 2 investigation and evaluation will normally be required by the Department for those exposure pathways for which the RBSLs are exceeded.
- For the dermal contact/ingestion/inhalation of surface soil contamination exposure pathways only, if the contaminant concentrations for all COCs are less than the RBSLs, then no additional actions will normally be required by the Department. If the maximum contaminant concentrations are greater than the RBSLs for any COCs, the Department will normally require active remediation to address the pathway(s) levels (see DEQ Environmental Guidance Document 06-205: Management of Petroleum Contaminated Materials for disposal direction).

This page intentionally left blank

SECTION 9.0 – TIER 2 EVALUATION

9.1 – STEP 1: IDENTIFICATION OF DATA NEEDS AND COLLECTION OF DATA

When a site is required to proceed with a Tier 2 assessment, additional contaminant and site data are needed. This information is used in the calculation of Tier 2 SSTLs. The information to be collected is dependent on the exposure pathway(s) being investigated. The data requirements are discussed in Section 6.0.

9.2 – STEP 2: DEVELOPMENT OF SITE CONCEPTUAL EXPOSURE SCENARIO

Under the Tier 1 evaluation, a Site Conceptual Exposure Scenario was developed to identify the complete exposure pathways. This scenario must be revised for the Tier 2 evaluation. In most cases, the Site Conceptual Exposure Scenario for Tier 2 will be the same as for Tier 1.

9.3 – STEP 3: INPUT PARAMETERS FOR TIER 2 SSTLS

The Tier 2 assessment requires the use of the same models as the Tier 1 assessment. However, site-specific fate and transport parameter values are used to calculate Tier 2 SSTLs, whereas Tier 1 RBSLs were generated using non-site-specific default values.

9.3.1 – Physical & Chemical Properties of COCs

The Department uses the same default values for the calculation of Tier 2 SSTLs as used for the generation of Tier 1 RBSLs; values can be found in Table D-1, Appendix D.

9.3.2 – Exposure Factors

The Department uses the same default values for residential and commercial exposure factors in Tier 2 as used in Tier 1; values can be found in Table D-3, Appendix D.

9.3.3 – Toxicity Values & Target Risk Limits

The Department uses the same default toxicity values and target risk limits for carcinogenic and noncarcinogenic health effects in Tier 2 as in Tier 1; values can be found in Table D-2, Appendix D.

9.3.4 – Fate & Transport Parameters

The Department allows the use of representative site-specific values for fate and transport parameters for Tier 2 that were not allowed at the Tier 1 level. These variables are labeled as “Site-Specific” under the “Tier 2 Value” column in Table D-4, Appendix D.

9.4 – STEP 4: CALCULATION OF TIER 2 SSTLS

Tier 2 SSTLs are calculated by the Department for selected POCs using computational software developed by the Department.

9.5 – STEP 5: CALCULATION OF REPRESENTATIVE CONCENTRATIONS

The SSTLs are compared to the representative contaminant concentrations discussed in Section 7.8. The representative concentrations are either the maximum or average contaminant concentrations, depending on the exposure pathway being examined.

9.6 – STEP 6: SELECTION OF THE NEXT COURSE OF ACTION

The possible outcomes of the Tier 2 evaluation are as follows:

- Site closure.
- RP notified of SSTLs and remedial actions required.
- Monitoring for a finite period of time to verify representative contaminant concentrations.

Details of actions that may be required are expressed below:

- If the representative concentrations for all COCs are less than the SSTLs for the applicable exposure pathways, then no additional actions would normally be required by the Department.
- Where the representative site concentrations are above any of the SSTLs for an exposure pathway, active cleanup to the SSTLs will normally be required. Remedial actions will proceed as detailed in Title 118 Appendix B, Steps 9 – 11.
- The use of engineered controls may be considered to eliminate actual or potential exposures.

SECTION 11.0 – GLOSSARY

applicable exposure factors - data used to calculate some allowable intake concentration of a chemical of concern into the body, including such factors as body weight, exposure duration, ingestion rate, etc.

biodecay – see biodegradation

biodegradation - the reduction in total mass and concentration of chemicals of concern due to the biological processes by bacteria in the environment.

chemical of concern (COC) - specific constituent of petroleum that the Department has identified for evaluation due to its toxicological effects.

commercial - refers to land use or exposure factors under conditions that cannot be defined as “residential” where receptors are potentially exposed to COCs.

direct exposure pathway - exposure pathway where the point of exposure is in the source area, without a release to any other medium (e.g., dermal contact with contaminated surface soils).

enclosed space - structure (e.g., residence with basement) of limited access allowing for the potential collection and concentration of contaminant vapors in the structure’s breathing space.

exposure pathway - the course a chemical of concern travels from the source area(s) of a release to a potentially exposed receptor, comprised of a release source (e.g., LUST), a transport medium or media (e.g., ground water), a point of exposure (e.g., a water well) and an exposure route (e.g., ingestion of contaminated ground water).

fate and transport model - an estimate of contaminant concentration with time and distance based on a quantitative estimate of chemical mobility and persistence, developed using pre-set or site-specific information in conjunction with analysis of transport mechanisms such as advection, dispersion, and diffusion and/or a quantitative estimate of biodegradation processes.

free product - measurable (≥ 0.01 feet) petroleum product that is present as a non-aqueous phase liquid (i.e., liquid not dissolved in ground water).

habitable – intended for human occupancy as a residence or workplace.

Hazard Index (HI) - the sum of two or more hazard quotients for multiple chemicals of concern or multiple exposure pathways, or both.

Hazard Quotient (HQ) - the ratio of the level of exposure of a chemical of concern over a specified time period to a reference dose for that chemical of concern derived for a similar period of time.

indirect exposure pathway - an exposure pathway with at least one intermediate release to any media between the source area and point of exposure (e.g., ingestion of contaminated ground water at a water well, generated from contaminated soils located in the upgradient direction of ground water flow).

Individual Excess Lifetime Cancer Risk (IELCR) - the target risk level for a carcinogenic chemical of concern (as in 10^{-6}) used to quantify risk in the RBCA process or establish risk-based screening levels.

Look-Up Table (LUT) - table containing Tier 1 RBSLs used for comparison to contaminant concentrations found during the Tier 1 site assessment.

monitoring well – a water well installed in accordance with Nebraska DHHS Title 178 within or straddling the ground water table for the purpose of collecting ground water samples for analysis.

monitoring (sampling) point – either a monitoring well, borehole, or similar structure (e.g., direct push boring, soil gas point) used for the collection of various environmental media (i.e., ground water, soil, soil vapor) for analysis.

natural attenuation - the reduction in total mass and concentration of chemicals of concern with distance and time due to processes such as biodegradation, diffusion, dispersion and absorption.

non-aqueous-phase liquid (NAPL) - see free product.

point of compliance (POC) - location between a source area and a potential point of exposure where concentrations of chemicals of concern must be at or below the determined target levels in the media of concern.

point of exposure (POE) - point at which a chemical of concern may come into contact with or be taken into an actual or potential receptor.

receptor - any human who is or may be adversely affected by a petroleum release.

recharge area – area where there is a downward component to hydraulic head and infiltrating water travels into deeper levels of the aquifer.

Remedial Action Class (RAC) - one of three pollution occurrences defined for categories of ground water (or overlying soils) in Nebraska, dependent on the degree (or potential) of use of ground water as drinking water, and further defined in DEQ Title 118 - Ground Water Quality Standards and Use Classification.

residential - refers to land use or exposure factors used to describe or characterize receptors that are potentially exposed to COCs in at least one of the following environments: residences, ground-level or basement apartments, or other similar domiciles, and sensitive population centers, including but not limited to daycare centers, schools, hospitals, or nursing homes.

risk assessment - an analysis of the potential for adverse health effects caused by a chemical of concern, used to determine the need and type of remedial action and/or to develop site-specific cleanup levels.

risk-based corrective action (RBCA) - a streamlined approach to petroleum release corrective actions in which exposure and risk assessment practices are integrated with traditional corrective actions to ensure that appropriate and cost-effective remedies are selected that are protective of human health and the environment.

risk-based screening level (RBSL) - initial corrective action target concentration for a chemical of concern for the first tier of risk assessment, calculated from simple and conservative fate and transport models and pre-set site conditions.

site-specific target level (SSTL) - corrective action target concentration or final cleanup level for a chemical of concern developed during the second tier of risk assessment, calculated from the same fate and transport models used to develop an RBSL, using site-specific information.

source area - either the location of liquid or residual petroleum hydrocarbons from a point source release or the location of the highest soil and ground water contaminant concentration of the chemicals of concern as determined by the site assessment.

structures, subsurface – enclosed manmade spaces located partially or wholly below ground level. Includes utility conduits, such as storm or sanitary sewers, as well as basements, crawl spaces, or other habitable structures.

subsurface soils - those unconsolidated materials located within the unsaturated zone at a depth greater than three feet below ground level.

surface soils - those unconsolidated materials located within the unsaturated zone at a depth between zero and three feet below ground level.

target risk limit - level of concern used in exposure equations for carcinogens (e.g., a 10^{-6} IELCR) or non-carcinogens (e.g., a HI=1) to calculate an allowable intake of a chemical of concern into the body.

Tier 1 assessment - a risk-based analysis to develop non-site-specific values (RBSLs) for direct and indirect exposure pathways utilizing conservative factors and fate and transport models for various potential exposure pathways, where the values will apply to all releases that fall within specific categories.

Tier 2 assessment - a risk-based analysis applying the direct exposure factors established under a Tier 1 evaluation at the point(s) of exposure developed for a specific site and development of SSTLs for potential indirect exposure pathways at a POE based on site-specific conditions.

Appendix A:
PAH Evaluation Using Total Hydrocarbons Analysis

SURROGATE METHOD FOR THE CONVERSION OF PAH RBSLS TO THE DEFAULT TEH VALUES

Due to potential difficulties with achieving the minimum quantification levels required by the Department for the polycyclic aromatic hydrocarbons (PAH) chemicals of concern (naphthalene, pyrene and benzo(a)pyrene), the Department developed an alternate method for the Tier 1 site screening of these chemicals using a Total Extractable Hydrocarbon (TEH) analysis method. In this surrogate method, default TEH risk-based screening levels (RBSLs) are developed based on the chemical-specific RBSLs and the assumed concentration of the chemical in the original product.

DIESEL FUEL

It is assumed here that diesel fuel contains the PAH chemicals of concern in the following percentages (by weight):

Naphthalene	0.2%
Pyrene	0.001%
Benzo(a)pyrene	0.001%

TEH values for each chemical-specific RBSL were calculated by dividing the RBSL by the percentage of the chemical in the product, providing a relative TEH level for the chemical concentration. For each exposure pathway, the lowest TEH value calculated was chosen as the default "TEH as Diesel" RBSL found in the Tier 1 Look-Up Tables.

The TEH values calculated for each chemical-specific RBSL are found in the accompanying tables in this appendix. The values used in the Tier 1 Look-Up Tables are shown in bold typeface.

WASTE OIL

It is assumed here that waste oil contains the PAH chemicals of concern in the following percentages (by weight):

Naphthalene	0.0%
Pyrene	0.0%
Benzo(a)pyrene	0.003%

Since benzo(a)pyrene (BaP) is the only PAH chemical of concern typically associated with waste oil, TEH values were calculated by dividing the BaP RBSL, where applicable, by the percentage of BaP in the product, providing a relative TEH level for BaP. For each applicable exposure pathway of concern, this TEH value was used as the default "TEH as Waste Oil" RBSL found in the Tier 1 Look-Up Tables.

The TEH values calculated for each BaP RBSL are found in the accompanying tables in this appendix, indicated by the bold typeface.

Table A-1. PAH as TEH Values: Ground Water Ingestion Exposure Pathway

EXECUTIVE SUMMARY

Facility or file name:	
Current facility name (if different from above):	
Facility address or site location:	
Status of fuel storage/distribution:	<input type="checkbox"/> Active <input type="checkbox"/> Inactive <input type="checkbox"/> NA
Is surface soil contamination present?	<input type="checkbox"/> Yes <input type="checkbox"/> No
Are subsurface soils impacted?	<input type="checkbox"/> Yes <input type="checkbox"/> No
Is ground water impacted?	<input type="checkbox"/> Yes <input type="checkbox"/> No <input type="checkbox"/> NA
Has the source(s) of release been identified?	<input type="checkbox"/> Yes <input type="checkbox"/> No
Was free product detected during the Tier 1 investigation?	<input type="checkbox"/> Yes <input type="checkbox"/> No
If yes, was the free product plume fully delineated?	<input type="checkbox"/> Yes <input type="checkbox"/> No
Were vapors detected in any on-site subsurface structures?	<input type="checkbox"/> Yes <input type="checkbox"/> No
Has surface water been impacted by the release?	<input type="checkbox"/> Yes <input type="checkbox"/> No
Were emergency actions initiated?	<input type="checkbox"/> Yes <input type="checkbox"/> No
Average depth of contamination in subsurface soils:	_____ ft _____ cm
Shallowest depth to ground water:	_____ ft <input type="checkbox"/> Not measured
Average depth to ground water:	_____ ft <input type="checkbox"/> Not measured
Distance to nearest drinking water supply well:	_____ ft <input type="checkbox"/> municipal <input type="checkbox"/> domestic
Distance to nearest non-potable water supply well:	_____ ft type: _____
Distance to nearest downgradient water supply well:	_____ ft <input type="checkbox"/> municipal <input type="checkbox"/> domestic
Is there evidence of vertical migration of the contaminant plume?	<input type="checkbox"/> Yes <input type="checkbox"/> No <input type="checkbox"/> NA

Statement of Completion & Responsible Party/Consultant Signature Block

The consultant representative acknowledges that this report meets the minimum requirements for a Tier 1 investigation at this petroleum release site, as specified in the Department's Risk-Based Corrective Action (RBCA) at Petroleum Release Sites: Tier 1/Tier 2 Assessments and Reports Guidance Document. Any procedures that differ from the guidance document specifications are noted in the report, were approved by the Department and are accompanied by appropriate documentation. The responsible party acknowledges that they have read (or discussed with their consultant), this site investigation report and are aware of their responsibility for the timely submission to the Department.

GROUND WATER AND SURFACE WATER USE

Ground Water - Current Use

Well Designation	Well Type/Use	Distance (ft)	Direction

Surface Water - Current Use

Surface Water Type	Beneficial Use	Distance (ft)	Direction

Ground Water & Surface Water - Future Use

Are the RP, current property owner (if different than RP), adjacent landowners, and/or local municipal authorities aware of potential future ground and/or surface water use development within the next five years?

Ground Water *Surface Water*
 Yes No Yes No

If yes, provide the following information. Include contact information in Notes below and/or Form 5b.

Location	Type of New Use

NOTES: 1) Justify choice of future ground water use; also indicate if water supply well may have some influence over vertical migration of plume.
 2) Justify choice for future surface water use and type of water body.

Recommended attachments: Area map with well and surface water locations.

INSTRUCTIONS FOR INVESTIGATION NARRATIVE

Note: The reporter may use a format of their choosing for the following narrative information, with the provision that all the minimum information requirements listed below are provided under the following headings and in the order outlined. Place the narrative behind a copy of this Investigation Form in the Tier 1 Report.

- I. Brief history of any abatement/remedial actions taken prior to initiating the Tier 1 investigation
- II. Summary of site characteristics
 - A. Site Location
 - B. General site topography, geology, and hydrogeology
- III. Summary of drilling activities
 - A. Date/method/equipment
 - B. Drilling order of boreholes
 - C. Drilling complications (e.g., auger failure or refusal, site recently modified), if any
 - D. Description of materials drilled through and evidence of contamination
 - E. Monitoring well installation
 - depth of wells
 - filter pack and grout materials
 - screened interval
 - type of well head protection
 - well development methodology, duration, estimated water removed
 - other information
 - F. Monitoring well location information
 - nature and location of permanent benchmark to which wells are referenced (designate on site map)
 - method (e.g., stadia, measuring wheel, tape) and measurements (in tabular format) used to reference wells to benchmark
 - G. Other information related to drilling activities (e.g., start/stop times for drilling & well installation)
- IV. Direct push technologies
 - A. Date/method/equipment
 - B. Order of probe locations
 - C. Description of materials drilled through and evidence of contamination
 - D. Other information related to direct push activities (e.g., start/stop times, media investigated)
- V. Summary of sampling activities
 - A. Soil sampling
 - method of sample collection
 - method/protocol used for head space analysis
 - method/protocol used for laboratory sample preparation
 - B. Ground water sampling
 - purging method/protocol/criteria (includes rationale for not purging, if applicable)
 - sample collection method/protocol
 - order of well sampling (Note: sample least contaminated to most contaminated)
 - C. Drinking water supply well/system sampling
 - location of sampling point (e.g., directly from well, outdoor tap, indoor tap)
 - purging method/protocol/criteria
 - sample collection method/protocol
 - D. QA/QC considerations
 - steps taken to limit cross-contamination between sampling locations
 - number/type/location of duplicates/blanks
 - decontamination protocol and other measures taken to minimize cross-contamination
- VI. Other information
 - A. Rationale for variances from approved work plan or RBCA guidance document
 - B. Contact information (i.e., names, phone numbers, affiliations) for people providing information gathered during investigation

If yes, was the free product removed prior to Tier 2 investigation?	<input type="checkbox"/> Yes	<input type="checkbox"/> No	_____
Were vapors detected in any utilities?	<input type="checkbox"/> Yes	<input type="checkbox"/> No	_____
Has surface water been impacted by the release?	<input type="checkbox"/> Yes	<input type="checkbox"/> No	_____
Average depth of contamination in subsurface soils:	_____ ft	_____ cm	<input type="checkbox"/> NA
Shallowest depth to ground water:	_____ ft	<input type="checkbox"/> NA	
Average depth to ground water:	_____ ft	<input type="checkbox"/> NA	
Distance to nearest drinking water supply well:	_____ ft	<input type="checkbox"/> NA	
Distance to nearest non-potable water supply well:	_____ ft	<input type="checkbox"/> NA	
Distance to nearest downgradient water supply well:	_____ ft	<input type="checkbox"/> NA	
Is there evidence of vertical migration of the contaminant plume?	<input type="checkbox"/> Yes	<input type="checkbox"/> No	<input type="checkbox"/> NA

Statement of Completion & Responsible Party/Consultant Signature Block

The consultant representative acknowledges that this report meets the minimum requirements for a Tier 2 investigation at this petroleum release site, as specified in the Department's Risk-Based Corrective Action (RBCA) at Petroleum Release Sites: Tier 1/Tier 2 Assessments and Reports Guidance Document. Any procedures that differ from the guidance document specifications are noted in the report, were approved by the Department and are accompanied by appropriate documentation. The responsible party acknowledges that they have read (or discussed with their consultant), this site investigation report and are aware of their responsibility for the timely submission to the Department.

INSTRUCTIONS FOR INVESTIGATION NARRATIVE

Note: The reporter may use a format of their choosing for the following narrative information, with the provision that all the minimum information requirements listed below, as it pertains to the exposure pathways investigated, are provided under the following headings and in the order outlined. Place the narrative behind a copy of this investigation form in the Tier 1 report.

- I. Brief history of any abatement/remedial actions taken prior to initiating the Tier 2 investigation
- II. Summary of site characteristics
 - A. Site Location
 - B. General site topography, geology, and hydrogeology
- III. Summary of drilling activities
 - A. Date/method/equipment
 - B. Drilling order of boreholes
 - C. Drilling complications (e.g., auger failure or refusal, site recently modified), if any
 - D. Description of materials drilled through and evidence of contamination
 - E. Monitoring well installation
 - depth of wells
 - filter pack and grout materials
 - screened interval
 - type of well head protection
 - well development methodology, duration, estimated water removed
 - other information
 - F. Monitoring well location information
 - nature & location of permanent benchmark to which wells are referenced (designate on site map)
 - method (e.g., stadia, measuring wheel, tape) and measurements (in tabular format) used to reference wells to benchmark
 - G. Other information related to drilling activities (e.g., start/stop times for drilling & well installation)
- IV. Direct push technologies
 - A. Date/method/equipment
 - B. Order of probe locations
 - C. Description of materials drilled through and evidence of contamination
 - D. Other information related to direct push activities (e.g., start/stop times, media investigated)
- V. Summary of sampling activities
 - A. Soil sampling
 - method of sample collection
 - method/protocol used for head space analysis
 - method/protocol used for laboratory sample preparation
 - B. Ground water sampling
 - purging method/protocol/criteria (includes rationale for not purging, if applicable)
 - sample collection method/protocol
 - order of well sampling (Note: sample least contaminated to most contaminated)
 - C. Drinking water supply well/system sampling
 - location of sampling point (e.g., directly from well, outdoor tap, indoor tap)
 - purging method/protocol/criteria
 - sample collection method/protocol
 - D. Soil vapor sampling
 - sample point installation (e.g., probe rod, vapor monitoring well)
 - purging method/protocol/criteria
 - sample collection method/protocol
 - E. QA/QC considerations
 - steps taken to limit cross-contamination between sampling locations
 - number/type/location of duplicates/blanks
 - decontamination protocol and other measures taken to minimize cross-contamination
- VI. Other information
 - A. Rationale for variances from approved work plan or RBCA guidance document
 - B. Contact information (i.e., names, phone numbers, affiliations) for people providing information gathered during investigation

Appendix E:
Fate & Transport Equations

Table E-1. Allowable Ground Water Concentrations for a POE

For a RAC-1 release, the allowable ground water concentration at a drinking water point of exposure (C_{poe}) is equal to the COC-specific MCL or some other standard selected by the Department for a COC not having an MCL. For non-drinking water wells, the allowable concentration is equal to 10 times the MCL or other selected standard.

For a RAC-2 release, C_{poe} is equal to a calculated risk-based target level for water ingestion based on the following:

<p>Carcinogenic effects</p> $RBTL_{gw} = \frac{TR \cdot BW \cdot AT_c \cdot 365}{IR_w \cdot ED \cdot EF \cdot SF_o}$	<p>Non-carcinogenic effects</p> $RBTL_{gw} = \frac{THQ \cdot BW \cdot AT_{nc} \cdot 365 \cdot RfD_o}{IR_w \cdot ED \cdot EF}$
--	---

where:

- RBTL_{gw} = Risk-based target level for ground water ingestion [mg/L]
- TR = Target risk or the increased chance of developing cancer over a lifetime due to exposure to a COC [-]
- THQ = Target Hazard Quotient for individual non-carcinogenic constituents [-]
- BW = Body weight [kg]
- AT_c = Averaging time for a carcinogen [years]
- AT_{nc} = Averaging time for a non-carcinogen [years]
- IR_w = Water ingestion rate [L/day]
- ED = Exposure duration [years]
- EF = Exposure frequency [days/year]
- SF_o = Chemical-specific oral cancer slope or potency factor [mg/(kg-day)]⁻¹
- RfD_o = Chemical-specific oral reference dose [mg/(kg-day)]

Table E-2. Ground Water Concentration at a Source and a POC Protective of Drinking Water

Concentration in ground water at the source:

$$C_{gw,source} = C_{poe} \cdot CRF_{sat,poe}$$

Concentration in ground water at a point of compliance:

$$C_{gw,poc} = C_{poe} \cdot \frac{CRF_{sat,poe}}{CRF_{sat,poc}}$$

where:

- $C_{gw,source}$ = RBSL calculated in the source area [mg/L]
- $CRF_{sat,poe}$ = Concentration reduction factor in the saturated zone between a source area and a point of exposure [(mg/L)/(mg/L)]
- $CRF_{sat,poc}$ = Concentration reduction factor in the saturated zone between a source area and a point of compliance [(mg/L)/(mg/L)]
- C_{poe} = Allowable contaminant concentration at the point of exposure [mg/L]

The CRF_{sat} is estimated using a simplified version of **Domenico's model*** that assumes (i) an infinite source; (ii) uniform, one-dimensional flow; (iii) first-order biodecay; and (iv) the receptor location directly downgradient from the source. The specific form of Domenico's model used is:

$$\frac{C(x)}{C_o} = \exp\left\{\frac{x}{2a_x} \left[\frac{l}{v} - \sqrt{1 + \frac{4la_x}{v^2}} \right]\right\} \cdot \operatorname{erf}\left\{\frac{W_y}{4\sqrt{a_y x}} \sqrt{\frac{l}{v}}\right\} \cdot \operatorname{erf}\left\{\frac{d_{gw}}{2\sqrt{a_z x}} \sqrt{\frac{l}{v}}\right\}$$

where:

- C = Dissolved-phase concentration [mg/L]
- C_o = Dissolved-phase concentration at the source (x=y=z=0) [mg/L]
- v = Retarded seepage velocity for a chemical [cm/day]
= Darcy Velocity / (Retardation Factor x Total Porosity)
- l = Overall first-order decay rate [day^{-1}]
- a_x = Longitudinal dispersivity = x/10 [cm]
- a_y = Lateral dispersivity = x/30 [cm]
- a_z = Vertical dispersivity = x/100 [cm]
- x, y, z = Spatial coordinates [cm]
- x = Distance along the center line from the downgradient edge of the dissolved-plume source zone or source well [cm]
- W_y = Width of source area perpendicular to ground water flow [cm]
- d_{gw} = Ground water mixing zone thickness [cm]

Retarded seepage velocity: $v = \frac{K' i}{R' Q_{TS}}$

where:

K = Hydraulic conductivity [cm/year]

i = Hydraulic gradient [--]

R = Retardation factor [--]

Q_{TS} = Total porosity in the unsaturated zone [cm^3 -voids/ cm^3 -soil]

Retardation factor: $R = 1 + \frac{r_{ss}' K_{ds}}{Q_{TS}}$

where:

r_{ss} = Dry bulk density of soil in the saturated zone [g/cm^3]

K_{ds} = Soil-water partition coefficient in the saturated zone [cm^3 -water/g-soil] = $f_{ocs} \times K_{oc}$

f_{ocs} = Fractional organic carbon content in the saturated zone soil [g-C/g-soil]

K_{oc} = Carbon-water partition coefficient [cm^3 -water/g-c]

Q_{TS} = Total porosity in the saturated zone [cm^3 -voids/ cm^3 -soil]

If a particular chemical is assumed not to biodecay (i.e., $l = 0$), $\frac{C(x)}{C_o}$ is equal to the result of the error function.

Please note that the CRF_{sat} is actually equal to $\frac{C_o}{C(x)}$.

Table E-3. Soil Concentration Protective of Drinking Water

Allowable soil concentration: $C_{soil} = C_{poe} \cdot CRF_{sat,poe} \cdot CRF_{mix} \cdot CRF_{unsat} \cdot ECF$

where:

- C_{soil} = Allowable source soil concentration [mg/kg]
- C_{poe} = Allowable ground water concentration at the point of exposure [mg/L]
- $CRF_{sat,poe}$ = Concentration reduction factor in the saturated zone [(mg/L)/(mg/L)]
- CRF_{mix} = Concentration reduction factor in the mixing zone [(mg/L)/(mg/L)]
- CRF_{unsat} = Concentration reduction factor in the unsaturated zone [(mg/L)/(mg/L)]
- ECF = Equilibrium conversion factor [(mg/kg-soil)/(mg/L-water)]

Concentration reduction in the mixing zone: $CRF_{mix} = 1 + \frac{U_{gw} \cdot d_{gw}}{IW_x}$

where:

- U_{gw} = Ground water Darcy Velocity [cm/year]
- = Hydraulic conductivity [cm/year] x Hydraulic gradient [--]
- d_{gw} = Ground water mixing zone thickness [cm]
- I = Infiltration rate of water through soil [cm/year]
- W_x = Length of source area parallel to ground water flow [cm]

Concentration reduction in the unsaturated zone is empirically estimated in Tier 1:

- $CRF_{unsat} = 1$ for depth to ground water ≤ 50 feet
- $CRF_{unsat} = 2$ for depth to ground water > 50 feet

Equilibrium conversion factor: $ECF = \frac{r_s \cdot K_d + Q_{ws} + Q_{as} \cdot H}{r_s}$

where:

- r_s = Dry bulk density of soil [g/cm³]
- K_d = Soil-water partition coefficient [cm³-water/g-soil] = $f_{ocs} \times K_{oc}$
- f_{ocs} = Fractional organic carbon content [g-C/g-soil]
- K_{oc} = Carbon-water partition coefficient [cm³-water/g-c]
- Q_{ws} = Volumetric water content in the vadose zone [cm³/cm³]
- Q_{as} = Volumetric air content in the soil [cm³/cm³]
- H = Henry's Law coefficient [(mg/L-water)/(mg/L-air)]

**Table E-4. Allowable Enclosed Space Breathing Zone
COC Concentrations for Indoor Inhalation**

To calculate allowable subsurface soil and ground water RBSLs protective of the enclosed space inhalation pathways of concern, target levels for contaminant concentrations within the enclosed space breathing zone must first be determined. These target levels are calculated based on the following:

<u>Carcinogenic effects</u>	<u>Non-carcinogenic effects</u>
$RBTL_{ai} = \frac{TR \cdot BW \cdot AT_c \cdot 365}{IR_i \cdot ET_i \cdot ED \cdot EF \cdot SF_i}$	$RBTL_{ai} = \frac{THQ \cdot BW \cdot AT_{nc} \cdot 365 \cdot RfD_i}{IR_i \cdot ET_i \cdot ED \cdot EF}$

where:

- RBTL_{ai} = Risk-based target level for indoor air [mg/m³]
- TR = Target risk or the increased chance of developing cancer over a lifetime due to exposure to a chemical of concern [--]
- THQ = Target Hazard Quotient for individual non-carcinogenic constituents [-]
- BW = Body weight [kg]
- AT_c = Averaging time for a carcinogen [years]
- AT_{nc} = Averaging time for a non-carcinogen [years]
- IR_i = Indoor inhalation rate [m³/hour]
- ET_i = Exposure time for indoor inhalation [hours/day]
- ED = Exposure duration [years]
- EF = Exposure frequency [days/year]
- SF_i = Chemical-specific inhalation cancer slope or potency factor [mg/(kg-day)]⁻¹
- RfD_i = Chemical-specific inhalation reference dose [mg/(kg-day)]

Table E-5. Soil Gas Concentrations Protective of Indoor Inhalation

Once $RBTL_{ai}$ has been determined (see Table E-4), this value is used to calculate an allowable soil vapor gas concentration outside the enclosed indoor space in source-zone soils, at a non-source-zone soil-vapor sampling point, and at the ground water table, using the following relationships:

Soil source:
$$C_{v,s} = RBTL_{ai} \cdot 10^{-3} \cdot \frac{h \cdot N \cdot L_s}{f \cdot 86400 \cdot D_s^{eff}} + 1 \frac{\mu\text{g}}{\text{L}}$$

Vapor sampling point:
$$C_{v,v} = RBTL_{ai} \cdot 10^{-3} \cdot \frac{h \cdot N \cdot L_{s,v}}{f \cdot 86400 \cdot D_s^{eff}} + 1 \frac{\mu\text{g}}{\text{L}}$$

At the ground water table:
$$C_{v,gw} = RBTL_{ai} \cdot 10^{-3} \cdot \frac{h \cdot N \cdot L_{gw}}{f \cdot 86400 \cdot D_w^{eff}} + 1 \frac{\mu\text{g}}{\text{L}}$$

where:

- $C_{v,s}$ = Vapor concentration in subsurface source soil [mg/L]
- $C_{v,v}$ = Vapor concentration in subsurface soil where the soil vapor sample is collected [mg/L]
- H = Height of the indoor space [cm]
- N = Volume of air changes per day [day^{-1}]
- L_s = Depth to chemical in soil [cm]
- $L_{s,v}$ = Depth to soil-vapor sampling point [cm]
- L_{gw} = Depth to the ground water table [cm]
- f = Fraction of the floor area through which diffusion occurs [--]
- D_s^{eff} = Chemical-specific effective diffusion coefficient in vadose zone soils [cm^2/s]
- D_w^{eff} = Chemical-specific effective diffusion coefficient between the ground water table and a structure [cm^2/s]
- $RBTL_{ai}$ = Risk-based target level for indoor air [mg/m^3]
- 86400 = Conversion factor from days to seconds
- 10^{-3} = Conversion factor from mg/m^3 to mg/L

Table E-6. Calculation of Effective Diffusivities

Chemical-specific effective diffusion coefficients in vadose zone soils, at the ground water table, and in capillary zone soils are calculated using the following relationships:

Vadose soils:
$$D_s^{eff} = D_a \cdot \frac{Q_{as}^{3.33}}{Q_T^2} + D_w \cdot \frac{1}{H} \cdot \frac{Q_{ws}^{3.33}}{Q_T^2}$$

At the ground water table:
$$D = \frac{L_{gw}}{\frac{h_{cap}}{D_{cap}^{eff}} + \frac{h_v}{D_s^{eff}}}$$

Capillary zone soils:
$$D_{cap}^{eff} = D_a \cdot \frac{Q_{acap}^{3.33}}{Q_T^2} + D_w \cdot \frac{1}{H} \cdot \frac{Q_{wcap}^{3.33}}{Q_T^2}$$

where:

- D_a = Chemical-specific diffusion coefficient in air [cm²/s]
- D_w = Chemical-specific diffusion coefficient in water [cm²/s]
- D_s^{eff} = Effective diffusivity in vadose zone soils [cm²/s]
- D_w^{eff} = Effective diffusivity above the ground water table [cm²/s]
- D_{cap}^{eff} = Effective diffusivity in capillary zone soils [cm²/s]
- Q_T = Total soil porosity in the impacted zone [cm³/cm³-soil]
- Q_{as} = Volumetric air content in the vadose zone [cm³-air/cm³-soil]
- Q_{ws} = Volumetric water content in the vadose zone [cm³-water/cm³-soil]
- Q_{acap} = Volumetric air content in the capillary zone [cm³-air/cm³-soil]
- Q_{wcap} = Volumetric water content in the capillary zone [cm³-water/cm³-soil]
- H = Henry's Law coefficient [(mg/L-water)/(mg/L-air)]
- L_{gw} = Depth to the ground water table [cm]
- h_{cap} = Capillary zone thickness [cm]
- h_v = Vadose zone thickness [cm]
- = $L_{gw} - h_{cap}$

Table E-7. Ground Water & Subsurface Soil Contaminant Concentrations Protective of Indoor Inhalation

For ground water:
$$RBSL_{winh} = \frac{C_{v,gw}}{H}$$

where:

- RBSL_{winh} = Allowable concentration in ground water protective of indoor inhalation [mg/L]
- C_{v,gw} = Vapor concentration above the ground water table [mg/L]
- H = Henry's Law coefficient [(mg/L-water)/(mg/L-air)]

For subsurface soils:
$$RBSL_{sinh} = \frac{C_{v,s}}{H} \cdot ECF$$

where:

- RBSL_{sinh} = Allowable concentration in ground water protective of indoor inhalation [mg/L]
- C_{v,s} = Vapor concentration above the ground water table [mg/L]
- H = Henry's Law coefficient [(mg/L-water)/(mg/L-air)]
- ECF = Equilibrium conversion factor [(mg/kg-soil)/(mg/L-water)], as presented in Table E-3

Table E-8. Surface Soil Contaminant Concentrations Protective of Outdoor Inhalation, Dermal Contact, and Ingestion of Vapors and Particulates

RBSLs for contaminated surface soils are determined using the following models:

Carcinogenic effects:

$$RBTL_{ss} = \frac{TR \cdot BW \cdot AT_c \cdot 365}{EF \cdot ED \cdot \left[(SF_o \cdot 10^{-6} \cdot (IR_s \cdot RAF_o + SA \cdot M \cdot RAF_d)) + (SF_i \cdot IR_o \cdot ET_o \cdot (VF_{ss} + VF_p)) \right]}$$

Non-carcinogenic effects:

$$RBTL_{ss} = \frac{THQ \cdot BW \cdot AT_{nc} \cdot 365}{EF \cdot ED \cdot \left[\frac{10^{-6} \cdot (IR_s \cdot RAF_o + SA \cdot M \cdot RAF_d)}{RfD_o} + \frac{IR_o \cdot ET_o \cdot (VF_{ss} + VF_p)}{RfD_i} \right]}$$

where:

- TR = Target risk or the increased chance of developing cancer over a lifetime due to exposure to a chemical of concern [--]
- THQ = Target Hazard Quotient for individual non-carcinogenic constituents [--]
- BW = Body weight [kg]
- AT_c = Averaging time for a carcinogen [years]
- AT_{nc} = Averaging time for a non-carcinogen [years]
- ED = Exposure duration [years]
- EF = Exposure frequency [days/year]
- IR_s = Soil ingestion rate [mg/day]
- RAF_o = Oral relative absorption factor [--]
- RAF_d = Dermal relative absorption factor [--]
- SA = Skin surface area [cm²/day]
- M = Soil-to-skin adherence factor [mg/cm²]
- IR_o = Outdoor inhalation rate [m³/hour]
- ET_o = Exposure time for outdoor inhalation [hours/day]
- SF_o = Chemical-specific oral cancer slope or potency factor [mg/(kg-day)]⁻¹
- SF_i = Chemical-specific inhalation cancer slope or potency factor [mg/(kg-day)]⁻¹
- RfD_o = Chemical-specific oral reference dose [mg/(kg-day)]
- RfD_i = Chemical-specific inhalation reference dose [mg/(kg-day)]
- VF_p = Volatilization factor of particulates [(mg/m³-air)/(mg/kg-soil)]
- VF_{ss} = Volatilization factor of particulates [(mg/m³-air)/(mg/kg-soil)]
- 10⁻⁶ = Conversion factor from milligrams to kilograms

Table E-9. Calculation of Volatilization Factors from Surface Soil

To calculate VF_{ss} , the volatilization factor from surface soils, use:

$$VF_{ss} = \frac{2 \cdot W_a \cdot r_s}{U_a \cdot d_a} \cdot \sqrt{10^3 \cdot \frac{D_s^{eff} \cdot H}{\rho \cdot t \cdot [Q_{ws} + (K_d \cdot r_s) + (H \cdot Q_{as})]}}$$

OR

$$VF_{ss} = \frac{W_a \cdot r_s \cdot d}{U_a \cdot d_a \cdot t} \cdot 10^3$$

NOTE: Use the smaller of the two results.

where:

- W_a = Width of source area parallel to wind flow direction [cm]
- r_s = Dry bulk density of soil [g/cm^3]
- U_a = Wind speed within breathing zone [cm/s]
- d_a = Breathing zone height [cm]
- D_s^{eff} = Effective diffusion coefficient in soil based on vapor-phase concentration [cm^2/s]
- H = Henry's Law coefficient [(mg/L-water)/(mg/L-air)]
- Q_{as} = Volumetric air content in the soil [cm^3/cm^3]
- Q_{ws} = Volumetric water content in the vadose zone [cm^3/cm^3]
- K_d = Soil-water partition coefficient [cm^3 -water/g-soil] = $f_{ocs} \times K_{oc}$
 f_{ocs} = Fractional organic carbon content [g-C/g-soil]
 K_{oc} = Carbon-water partition coefficient [cm^3 -water/g-c]
- t = Averaging time for vapor flux [s] = ED(years) x 365(days/year) x 86400(sec/day)
- d = Depth to base of surficial soil zone [cm]
- 10^3 = Conversion factor from [m^3 -g] to [cm^3 -kg]

To calculate VF_p , the volatilization factor of particulates, use: $VF_p = \frac{P_e \cdot W_a}{U_a \cdot d_a} \cdot 10^3$

where:

- P_e = Particulate emission rate [g-soil/ cm^2 -sec]
- W_a = Width of source area parallel to wind flow direction [cm]
- U_a = Wind speed within breathing zone [cm/s]
- d_a = Breathing zone height [cm]
- 10^3 = Conversion factor from [m^3 -g] to [cm^3 -kg]

Table E-10. Soil Saturation Level

In some instances, the calculated RBSL for an exposure pathway of concern involving surface or subsurface soils may be greater than the maximum contaminant concentration that could be expected for the specified exposure scenario, even if free phase product is present in the soil. The soil concentration at which equilibrated vapor and dissolved pore-water phases become saturated, C_s^{sat} , is described by the following:

$$C_s^{sat} = \frac{S}{r_s} \cdot [H \cdot Q_{as} + Q_{ws} + K_d \cdot r_s]$$

where:

- S = Pure component solubility in water [mg/L-water]
- r_s = Dry soil bulk density [g-soil/cm³-soil]
- H = Henry's Law coefficient [(mg/L-water)/(mg/L-air)]
- Q_{as} = Volumetric air content in the vadose zone [cm³-air/cm³-soil]
- Q_{ws} = Volumetric water content in the vadose zone [cm³-water/cm³-soil]
- K_d = Soil-water partition coefficient [cm³-water/g-soil] = $f_{oc} \times K_{oc}$
 - f_{oc} = Fractional organic carbon content [g-Carbon/g-soil]
 - K_{oc} = Carbon-water partition coefficient [cm³-water/g-Carbon]

Table E-11. Saturated Vapor Concentration

$$C_v^{sat} = \frac{P_v \cdot MW \cdot 10^3}{R \cdot T}$$

where:

- C_v^{sat} = Saturated vapor concentration [mg/L-air]
- P_v = Saturated vapor pressure [atm]
- MW = Molecular weight [g/g-mol]
- R = Ideal gas constant [L-atm/g-mol-K]
- T = Temperature [K]
- 10^3 = Conversion factor [mg/g]
